with swelling and pain over the area of the metatarsophalangeal joint. These symptoms were acute for one month, after which they partially subsided. Three months previous to examination they again became acute, and, while the patient was able to walk, the joint remained painful and tender. Examination revealed an area of swelling about the size of a quarter over the second metatarsophalangeal articulation. The skin over this area appeared normal. There was tenderness on palpation.

Roentgenograms showed deformity of the second metatarsophalangeal joint with increased widening and density of the second metatarsal and widening and deformity of the head of this bone. There was a similar involvement of the proximal end of the proximal phalanx of this toe (fig. 14).

KYPHOSIS DORSALIS JUVENILIS

Juvenile dorsal kyphosis was first described by Scheuermann⁵ in 1920 and is commonly designated as epiphysitis or osteochondritis of the spine. It occurs at about the age of puberty with a peak incidence at 15 to 16 years. The area most frequently involved is the middorsal spine, and there is often an associated rounded kyphosis in that area. Pain in the back, tenderness to pressure and fatigue are characteristic features. The pain is aggravated by the erect posture and relieved by bed rest.

On the roentgenogram the epiphyses appear of irregular density and may show fragmentation. They are fuzzy and indistinct in outline. There may be an increase in the clear space between the epiphysis and the vertebral body. The latter shows irregular calcification along its superior and inferior surfaces and also becomes wedged anteriorly. These changes indicate

Fig. 15 (case 6)—Dorsal kyphosis with irregularity of the vertebral margins and narrowing of the disks in a case of kyphosis dorsalis juvenilis.

disturbance in epiphysial growth with interruption of the normal ossification.

When proper therapeutic measures are instituted there is a disappearance of the fuzzy outlines and an

⁵ Scheuermann, H. Kyphosis Dorsalis Juvenilis, *Ugeskr. f. Læger* 5: 569-574, 1920.

increase in calcification of both the epiphyses and the vertebrae. In cases of minimal involvement there will be little residual deformity. Where the anatomic changes have been well defined there will be residual kyphosis of noticeable degree, and wedging of the vertebrae with irregularity along the margins will persist. The disks between the involved vertebrae also show narrowing.

Beadle,⁶ in his monograph on the intervertebral disks, points out that in the specimens collected by Schmorl many of these adolescent kyphoses were associated with prolapses of the disks in the nucleus region in the lower dorsal and lumbar areas. These prolapses tend to involve symmetrical areas in adjacent vertebrae occurring in a straight row one above the other and presenting a characteristic appearance. They are not similar to the prolapses seen in the adult spine, where the distribution is uneven. There is an associated kyphosis of varying degree in the lower dorsal area, with a corresponding lumbar lordosis. Beadle attributes the condition to a developmental error with defects in the cartilage plates, which are likely to give way under excessive strain or exercise. These defects allow passage of the nuclear material into the vertebral spongiosa. If the excessive exercise is not stopped at this point the process goes on to its final phase, a definite growth disturbance.

The different points of view as manifested first by Scheuermann, who believed that these cases represent osteochondritis analogous to similar lesions in other parts of the body, and later by Schmorl and Beadle, who believed that these lesions are secondary to prolapses of the disks in the nucleus region, have led to some discussion and controversy. I feel that lesions of both types may occur in different patients, depending on anatomic defects and other factors.

CASE 6.—H. S., a white girl aged 15 years, first seen in 1936, stated at that time that she had struck her back in a fall. She denied any previous back complaint. Examination showed that the patient was overweight, with exaggeration of the dorsal curve and a slight kyphosis in the cervicodorsal area. She complained of pain on palpation and percussion over the lower cervical and midthoracic areas. Flexion of the spine was limited, and there was moderate muscle spasm.

Roentgenograms of the spine showed a definite rounded dorsal kyphosis with irregularity in contour involving the vertebral bodies in the mid and lower dorsal areas and the lumbar area. There was also narrowing of the disks between most of these vertebrae. The vertebral epiphyses were ragged and irregular in appearance. Several of the vertebrae showed evidence of Schmorl's nodes.

Examination two years later showed the same rounded dorsal curve. The epiphyses were partly calcified, and the vertebral margins showed a residual irregularity. Some of the intervertebral disks were narrowed (fig. 15).

COMMENT

In this discussion I have attempted to correlate the findings in aseptic necrosis as it involves the developing epiphyses and the primary centers of ossification in certain of the short bones. Short descriptions are given of the salient points of some of the more commonly observed lesions. As the process may involve any of

the developing epiphyses, only brief mention of the various areas has been possible.

The etiology of aseptic necrosis is a fascinating problem, but no general agreement as to this phase of the subject has been reached. That some form of trauma with secondary vascular occlusion of the involved area is responsible is held by many. Embolic occlusion has also been mentioned as a cause, and endocrine dysfunction has been invoked by others.

The pathologic process probably involves actual death of the ossifying nucleus, followed by fragmentation, irregular absorption of the involved bone and replacement by so-called creeping substitution or recalcification. This is the same process that has been observed in adults, in whom aseptic necrosis is being increasingly recognized. The cartilage is in most instances not involved in the process. In general, the clinical findings are not prominent or acute and there may be no complaint except for slight pain and limping. There may be restriction of motion of the involved part.

The roentgen examination has been of the greatest aid in the study of the changing pathologic picture in these cases, as by this method it is possible to demon-

Aseptic Necrosis (Partial List)

Primary Centers	Secondary Centers
Vertebral body (Calvé 1925)	Vertebral epiphysis (Scheuermann 1921) Sternal end of clavicle (Friedrich 1924)
Carpal scaphoid (Preisler)	Head of humerus (Hass 1921) Capitulum of humerus (Panner 1927) Head of radius (Brailsford 1935)
Semilunar, adult (Klenböck 1910)	Ulna, distal (Burns 1931) Head of metacarpals (Mauelaira 1927) Iliac crest (Buchman 1925)
Patella (Köhler 1908)	Pubic symphysis (Van Neck 1924) Ischiopubic junction (Oldberg 1924)
Astragalus (Mouchet 1925)	Head of femur (Legg 1910) Trochanter of femur (Monde Felix 1922)
Tarsal scaphoid (Köhler 1908)	Patella (Stüding-Larsen 1921) Head of tibia (Ritter 1929)
Medial cuneiform (Buschke 1931)	Tubercle of tibia (Osgood, Schlatter 1903) Os calcis (Sever 1912) Metatarsals (Freiberg 1914)

strate the early evidences of decalcification, the subsequent necrosis and finally the signs of repair. In the earliest stages there are usually small areas of lessened density which under observation increase in extent and intensity. The epiphysis becomes fissured and fragmented and fuzzy in outline, with a ragged appearance. Areas of dense necrotic bone are visualized. The process may involve both the epiphysis and the metaphysis, and the former may be compressed and flattened. In the stage of regeneration or recovery there is a gradual loss of the osteoporosis with absorption of the dense necrotic bone in the epiphysis. This is followed by slowly advancing replacement of the necrotic bone by recalcification, which proceeds until there is complete bony restitution.

The amount of deformity of the restored bony contour will depend on many factors, including the stage at which it was first recognized and adequate treatment was applied. The duration of treatment also plays a role. Some patients refuse to allow the involved part adequate rest after the symptoms have disappeared. It should be recognized that there is a definite lag in bony replacement as compared with the disappearance of the symptoms. Many patients have a definite sense of well being at a time when the roentgenograms still show necrosis and very little evidence of regeneration.

THE CLINICAL DIAGNOSIS, TREATMENT AND PROGNOSIS OF EPIPHYSIAL DISTURBANCES IN CHILDHOOD

WALLACE H. COLE, M.D.

ST. PAUL

The etiology of epiphysial lesions is not clearly understood, and it is impossible with our present knowledge to classify these disturbances except on an anatomic basis, although there are some who feel that an endocrine dysfunction underlies most, if not all, of the group under consideration. However, a discussion of the etiology does not come within the scope of this paper. The name osteochondrosis has been applied, in the Standard Nomenclature of Disease, to most of the conditions involving growth centers the etiology of which is obscure or at least on which there is no unified opinion as to the cause, and our older and more familiar terms must be sidetracked for purposes of classification and filing if not otherwise.

The epiphyses throughout the body have, of course, a very regular and constant anatomic position, and their ossification is also constant for any particular location. Some, a very few, show centers already present at birth, while others may remain completely cartilaginous until puberty, and it is an understanding of these different periods of development which forms a basis for the recognition of any pathologic condition which may supervene.

In reviewing the cases with epiphysial disturbances from a rather large children's service, followed over a number of years, it was evident that, aside from lesions of the hip, knee and spine, these disturbances are fairly rare and relatively unimportant. The more common conditions will therefore be discussed first, but the radiographic changes and findings, so vitally important in making a definite diagnosis, will not be touched on as Dr. Doub has covered this part of the subject.

So much has been written about osteochondrosis of the head of the femur (Legg-Perthes disease) that in late years, in my experience, it has been rare to see a case which has not been diagnosed already by the family physician, although many cases on account of the mildness of the symptoms are allowed to go for many months by the parents before medical advice is sought. There have been more cases with infectious conditions, including tuberculosis, which have been diagnosed as Legg-Perthes disease than the reverse. Some cases certainly are never seen by a doctor and some may present such minor symptoms that when in later life a deformed hip is found because of developing disability no history of earlier trouble can be obtained. This has been seen by me in recruits when active physical training has brought out an insufficiency of the hip joint never before suspected. It is this insidiousness of onset which is largely responsible for the delay in proper treatment in many cases, and not neglect on the part of the parents or the physician.

Most cases can be diagnosed clinically with a fair degree of certainty, but the roentgenogram must decide in the end, if no mistakes are to be made. The condition is found predominantly in boys, and an examination of many reports shows that probably around 85 per cent of all patients are males. They are seen as young as 3 years of age and up into the teens, although an onset after 12 years is very rare. The

first symptom in a typical case is usually a limp which develops as the day goes on but is absent after and on first getting up in the morning. This limp is soon accompanied by tiring and discomfort, the latter of which may become definite pain, with reference to the region of the knee, at times. The symptoms, relieved by rest at first, gradually become more persistent and constant, and definite disability of the results. Usually, if the parents wait until this time before seeking medical aid, there has already developed some deformity of the upper end of the femur. Examination shows, even early in the disease, that there is limitation of the rotations, especially internally, and abduction. Flexion usually remains free, but there may be a slight limitation of hyperextension of the hip, which is noticeable if the test is made with the patient lying in the prone position. Forcing all motions may cause discomfort or even pain. Later findings may be atrophy of the thigh muscles and glutei and some shortening. As already mentioned, the roentgenogram will be the final evidence needed to insure the diagnosis.

The orthopedic treatment of osteochondrosis of the hip, if this term must be used, is based on the fact that the head of the femur is softened by the underlying pathologic condition and will become deformed if pressure is placed on it. Consequently, non-weight bearing is the first requirement of therapy. How this can be applied depends on the circumstances under which the patient is seen and the social and economic background. The ideal is to place the child in bed with light weight and pulley traction attached to the leg of the involved side so that absolutely no weight bearing is possible, and to continue this for months, or in some cases years, until the roentgenogram shows that healing has taken place. If the patient can be controlled properly the traction can be dispensed with toward the end and with some children may not be necessary from the beginning. I have found that in the later stages free motion of the hip and leg, with the body held firmly on a Bradford frame, seems to help prevent atrophy and apparently does no harm. As it is impossible to keep all children with this lesion in bed for the length of time needed to allow healing to take place, some substitutes must be found for the ideal. The ring-caliper splint has been found to be satisfactory in this regard, and weight bearing through the hip can certainly be cut to a minimum if the splint is well fitted. Results with a large number of cases treated in the outpatient department by this method have been very satisfactory. In the more acute cases the brace, instead of being fastened to a ferrule in the shoe, is extended to a foot piece or patten below the shoe, with the shoe on the normal side built up to equalize the length of the two sides. Crutches can be used to relieve some of the brace pressure on the tuberosity of the ischium, if desired. Complete fixation of a hip joint in plaster of paris is never indicated, unless for purposes of transportation.

The general treatment should consist of those measures necessary to keep the child in good health and the use of thyroid. It has been claimed that with early recognition of this condition adequate thyroid therapy will eliminate the necessity for protective treatment, but even if thyroid will hurry the healing process, and my limited experience makes me feel that it does, it is certain that non-weight bearing is essential also until the bone is firm enough to assume its full function.

The protection, of whatever kind, must be continued until the roentgenogram shows that the cycle of the

lesion has been completed and healing has taken place, and then gradual resumption of full activity can be allowed. There can be little doubt that a practically normal hip will result if the case has been seen early and proper protection has been used. Certainly further deformity of the head of the femur can be prevented, but it is questionable whether that deformity which is already present when the patient is first seen can be overcome. Those who show flattening and broadening of the capital epiphysis at the first examination will probably always have some distortion of the hip and a disability which, although negligible or absent at first, will become greater as the age increases. Even with the apparently perfect recoveries there will be a tendency toward the development of a degenerative arthritis in later life.

Slipping of the proximal femoral epiphysis is a lesion which will sometimes be confused clinically with osteochondrosis of the hip, but it presents enough characteristic symptoms and findings to differentiate it definitely from any other lesion. Here again so much has been written on the subject that only the most important factors need be reviewed. The condition occurs about twice as often in boys as in girls, and in close to 70 per cent of the cases the general body build is that which is frequently described as the Frölich type of individual, that is, the somewhat overgrown child with excessive subcutaneous fat, flabby muscles and genital hypoplasia. The smaller percentage of patients are apparently physically normal children or the tall and thin, rapidly growing type. The onset is usually very gradual with intermittent tiredness, discomfort and limp, which soon become more constant and are accompanied by stiffness of the hip joint. There may be pain in the knee early as with any pathologic condition of the hip joint.

Examination shows the extremity in some external rotation with a definite limitation of internal rotation and abduction. When the thigh is flexed on the trunk, it tends to go into external rotation and abduction, but hyperextension may be even freer than on the normal side. Palpation frequently reveals some apparent thickening over the joint, anteriorly. In all but the earliest cases there will be some shortening of the extremity, with elevation of the trochanter above Nélaton's line. All of these symptoms and clinical findings are due to a gradual slipping and rotation of the femoral head downward and backward on the neck. Following some injury or sudden motion, immediate and complete disability of the hip may occur as the result of acute slipping of the epiphysis from the neck, but the history will usually show that the prodromal symptoms were present long before.

The x-ray appearances in the usual case of slipping femoral epiphysis are typical of the condition in all stages, and even in the earliest case the films will confirm the clinical diagnosis if they are well taken and a lateral view is included. The lateral view is absolutely essential if mistakes are not to be made.

The prognosis for a normal or near normal hip is good only if the case is seen and diagnosed in the early stages with no delay in instituting proper treatment. Older cases all show some disability, sometimes of a pronounced degree.

Treatment, in addition to the use of thyroid or other endocrine product, is aimed at correction of the deformity and the prevention of further slipping after this has been accomplished. There is no unanimity of opinion as to the best methods for accomplishing these

aims, but as time goes on I find myself becoming therapeutically more and more conservative in the approach to these cases. Strong skeletal traction will reduce most of the acute slips and many of the chronic ones, although one must not expect to get a perfect contour, as the changes which take place in the shape of the neck and head and of the epiphysal disk during the gradual development of the lesion do not allow reposition with absolutely normal relationship of parts. In cases in which approximate reduction is obtained, and this may take several weeks, or in very early cases in which the slipping is as yet minimal, either lighter traction must be maintained until the epiphysal line closes or fixation of the head must be assured by operative means. Multiple drilling, sliver bone grafts through drill holes, a large bone graft, the Smith-Petersen nail and vitallium screws have all been used for this purpose and each has its advocates. There is probably not much choice between them, but it should never be forgotten that the operation, of whatever type, is only a means to an end, and that end is union of the epiphysis to the neck. Until this has taken place, recurrent slipping may happen at any time.

If reduction cannot be obtained by traction, one must decide whether to manipulate the hip, perform a radical operation immediately or wait until fusion of the epiphysis has occurred in the deformed position and then resort to some type of osteotomy. I have seen some excellent results from manipulation but many more poor ones, with stiffness amounting almost to ankylosis and not infrequently aseptic necrosis of the head. The same is true of open reduction of the head and of wedge osteotomy of the neck and I am therefore inclined to postpone radical treatment in these cases until a trochanteric osteotomy can be performed. In the meantime, progression of the lesion must be stopped by recumbency, with or without traction, or by the use of an efficient ring-caliper splint. The osteotomy will at least partially correct the deformity and will obviate the danger of further intra-articular pathologic change. Arthritic changes will, however, certainly appear later in life under any circumstances, although the nearer to normal the weight bearing lines can be placed the later will these changes occur. Radical treatment may be called for at this time if the disability becomes too great.

Disturbances of the epiphyses other than at the hip, which come under the classification of osteochondrosis, are of relative unimportance once the diagnosis has been made, but great care should always be taken to rule out more severe conditions with which they may be confused.

Vertebral epiphysitis, a condition in the spine probably analogous to Legg-Perthes disease in the hip, does not occur until puberty, as the epiphysal plates of the vertebral bodies develop at that time. Most cases are seen in boys between 14 and 17 years of age and the smaller group in girls somewhat earlier. There are backache and fatigue, with the gradual development of a rounded dorsal kyphosis. Only rarely is there any actual pain. Tuberculosis of the spine is the main lesion that must be ruled out, and the lack of acute symptoms and the rounded curve are the distinguishing differences. The roentgenogram makes the diagnosis clear. With no treatment the rounding of the spine may increase, but in the end this deformity is the only symptom, and as the spinal epiphyses may not unite to the bodies until early in the twenties there can be progression up to this time. Eighteen year old

boys with this condition therefore should not be accepted into the armed services; but after the epiphyses have united the deformity itself, unless very severe, should be no drawback. If seen and recognized early, part of the deformity, at least, can be prevented and the symptoms alleviated by recumbency, plaster of paris or brace support and active muscular exercise tending to strengthen and straighten the back.

Osteochondrosis of the tuberosity of the tibia (Osgood-Schlatter disease) is a fairly common condition seen usually in active adolescent boys which fortunately leads to no permanent disability. There is some thickening of the tubercle, with tenderness on pressure over this point and discomfort or pain on active use of the knee. Treatment aims to relieve the symptoms by rest and lessening of the pull on the patellar tendon, and thyroid may also be given. Strapping, splints and plaster of paris can be used but recovery occurs in all cases regardless of the therapy. Many cases are over-treated.

An osteochondrotic lesion similar to that at the tibial tubercle is found in the heel, the so-called apophysitis of the os calcis. Reducing the pull on the achilles tendon by raising the heel of the shoe is usually all the therapy needed, although in acute cases a short period of complete rest may be required at first. Healing always takes place and there is never any residual disability.

The other epiphysial disturbance in the foot of any importance is the involvement of the head of a metatarsal, almost always the second, with an osteochondrosis (Köhler's disease, Freiberg's infraction). Rest and protection relieve the symptoms quickly, and no disability results after the epiphysis has united. A full length steel in the sole of the shoe or an anterior arch bar usually is sufficient treatment. The lesion in the tarsal navicular to which Köhler's name is given, although similar in pathology, treatment and prognosis, is not, of course, in an epiphysis.

Time does not permit a discussion of the various epiphysial lesions which are due to congenital defects, definite infections and acute injury, which properly do not come under my subject but which must always be considered in making a differential diagnosis. If the possibilities are always kept in mind, the clinical and roentgenologic findings should make most diagnoses fairly certain.

25 West Fourth Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. DOUB AND COLE

DR. W. EDWARD CHAMBERLAIN, Philadelphia: Cloward and Bucy (*Am. J. Roentgenol.* 38:681 [Nov.] 1937) showed that there is a high incidence of spinal extradural cyst in cases of kyphosis dorsalis juvenilis, and that when both of these conditions are present the former is the cause of the latter. I'm sure we all agree with Dr. Doub when he classifies Legg-Perthes' disease of the hip, Osgood Schlatter's disease of the tibia, Köhler's disease of the tarsal, scaphoid and a score of similar involvements of other parts as manifestations of the same disease process differing only in location. For many years we have used the term "osteochondritis juvenilis" for all of these conditions, differentiating them from one another by adding a word or two for anatomic localization. Thus Legg-Perthes' disease becomes osteochondritis juvenilis of the hip; Köhler's disease becomes osteochondritis juvenilis of the tarsal scaphoid, and so on. We must question whether Dr. Doub's terminology "aseptic necrosis" should replace the older terminology, "osteochondritis juvenilis." The proved cases of "aseptic necrosis" in bone, visualized for us by Dr. Phemister and his co-workers,

and well displayed in Dr. Henry K. Taylor's scientific exhibit at this meeting, show a very different gross pathologic and roentgenographic appearance. Dead bone retains its calcium content, and were the primary underlying early change in this condition actually an aseptic necrosis would we not see the x-ray appearance of that condition? Instead, as Dr. Doub has shown, we find foci of demineralization as the earliest visible change. Only in those cases in which impaction has taken place do we see anything reminiscent of Phemister's aseptic necrosis picture, and in such cases the x-ray appearance is explained by the presence of the impaction. Dr. Doub's paper presents an excellent and thoughtful review of this important entity. Whether the name which he asks us to accept for it will stand the test of time is open to some question. We must look to the histopathologist for the answer to that question.

DR. FRANK R. OBER, Boston: I am not quite satisfied that these conditions should be called epiphysitis, especially in Scheuermann's disease. There are four types of spinal vertebrae which may be observed by taking lateral x-ray films of newborn infants. First there is the normal shaped vertebra, second the egg shaped vertebra, of which there may be several, the condition being more prominent in the lumbar region than in any other, third there is the one with the incisura and fourth there is one with a disturbance of the vertebral plates and on the anterior superior and inferior surfaces of each vertebra. The third and fourth types usually persist over a long period of time and may result in the so-called epiphysitis juvenilis, which is known as Scheuermann's disease. These two conditions represent a delay in the normal laying down of lime salts. The incisura defect is filled with fibrous tissue. Many of the cases in the fourth group show on physical examination an increased lumbar lordosis, and when the lumbar lordosis is increased the two curves above are always affected; that is, an increase in the normal kyphosis of the dorsal and a cervical lordosis of the cervical spine occurs. In most of these cases there is present a positive abduction sign and shortening of the posterior leg muscles. The pull of the contracted fascia of the thigh on the pelvis increases the lumbar lordosis and probably affects the spine, so that lime salts are not laid down as rapidly where there are no fascial contractures. Dr. Frank Dickson of Kansas City has done a fasciotomy in many of these cases, and the improvement on the so-called epiphysitis has been much more rapid than by many other methods. The point in the diagnosis of Legg-Perthes' disease is that if one inspects the hips one will notice that the contour of the trochanter is much more prominent on the affected side than on the other. The best treatment of Legg-Perthes' disease is the application of non-weight bearing splint in the singular cases and bed treatment in the double cases until the head shows signs of normal recovery. Otherwise, if these patients are allowed to bear weight, they may develop a misshapen head, acetabulum and a degenerative arthritis in people as young as 20. In a preslipped femoral epiphysis or a slightly slipped femoral epiphysis most of these patients will make an excellent recovery if allowed to walk on a non-weight bearing splint. At the Children's Hospital, Boston, Dr. William Green has treated a large series of cases of slipped femoral epiphysis by conservative measures, using balanced traction and Thomas splint. Operative methods do not always result in a normal useful hip joint.

DR. DALLAS B. PHEMISTER, Chicago: As Dr. Doub mentioned, Axhausen was responsible for the first descriptions of the pathology of most of these necrosing lesions occurring in the epiphyses and short bones of children and adolescents. But aside from Kienböck's disease of the lunatum and Köhler's disease of the metatarsals he did not report the condition in adults. In the past eight years it has been recognized with increasing frequency in the epiphyses and shafts of the long bones of the extremities of adults. The lesion may occur singly or multiple in the epiphyses or shafts or in both locations. The essential pathologic change is blockage of the blood supply followed by necrosis of the bone without any evidence of infection in the necrotic area. The cause of the vascular blockage, whether local disease or embolism, was not known in about half of the reported cases; but in the remainder it was caisson disease, in which liberated nitrogen gas produced either embolism or, what appears less likely, direct pressure on the blood vessels within

the bone. As to diagnosis, the condition was long misinterpreted both pathologically and roentgenologically. The epiphysal lesions, nearly always confined to the heads of the femurs or humeri, are usually first recognizable in roentgenograms after the lapse of many months because of the breaking down of the weight bearing portions and of the density changes in the rest of the epiphysis due to creeping substitution of dead bone by new bone. The end result after some years is a deforming arthritis frequently containing osteocartilaginous loose bodies. The dead areas in the shaft undergo creeping replacement by new bone in their peripheral portions, but, if large, the central portions persist and undergo calcification, which makes them recognizable in roentgenograms because of increased density particularly about their margins. The changes are illustrated in the first autopsy reports published by Kahlstrom, Burton and myself seven years ago.

DR. H. P. DOUB, Detroit: The question is asked Where does the slipped epiphysis fit into this picture, and what relation does it bear to the other diseases which have been described? In my opinion slipped epiphysis fits exactly into the general picture of aseptic necrosis, having the same etiologic basis. Because of limitations of time discussion of this condition was omitted, but it will be included in the published paper. In a case of slipped epiphysis involving the capital epiphysis of the femur, the first sign is a slight widening of the epiphysal line, which is most apparent on films made in the lateral projection (this view is also important in Legg-Perthes' disease). As this widening of the epiphysal line increases in extent and irregularity, one should observe closely for the first signs of displacement of the epiphysis itself. It is unusual in these cases for the epiphysis to show necrosis, though this seems strange if the theory of disturbed vascular supply is to be accepted. It is true, as we all recognize, that the term aseptic necrosis is on trial. It is also true that the final result in aseptic necrosis of the developing epiphysis is different from that in the adult. The changes in the adult have been well shown by Dr. Phemister, who has done a great deal of work on this problem.

DR. W. H. COLE, St. Paul: There are two things mentioned by Dr. Ober that I should like to reemphasize. First, I don't believe anybody knows whether all of these conditions belong together or not. That is the reason why those responsible for the Standard Nomenclature of Disease use the word "osteochondrosis," in which they have put these cases, although not necessarily claiming that they all belong together. It is merely a convenient spot for them until the cause can be discovered and when we know whether they all belong to the same underlying condition or whether they are separate entities. Another point is that since we have started taking multiple x-rays of children who have epiphysal lesions every once in a while we do pick up lesions in other spots. Köhler mentioned finding it in the patella and in the foot in the same case. If we examine all the bones, we might find changes in other epiphyses which may not be giving any clinical symptoms.

Number of Hospital Beds in Korea.—In 1938 there were 149 hospitals in Korea. Four were large government institutions under the direct control of the government general, 50 were public establishments maintained by individual provinces or municipalities, approximately 20 were Christian mission hospitals and the remaining ones were private institutions, at least two thirds of which were owned by the Japanese. The large government and mission hospitals are located in the few important centers, and the provincial and mission hospitals, along with the private institutions, provide a network of small but well distributed plants throughout most of the peninsula. In addition to the hospitals mentioned there are numerous small so-called hospitals scattered over Korea; they have no beds and are essentially physicians' offices or dispensaries. On the basis of a population of 24,000,000 there is 0.3 hospital bed per thousand of population (United States, 9.7 per thousand of population). Obviously, such a number of beds is grossly insufficient for the needs of the local people.—Simmons, James S., and others: *Global Epidemiology*, Philadelphia, J. P. Lippincott Company, 1944.

THE COORDINATION OF MEDICAL AND BLUE CROSS PLANS

LESTER H. PERRY

HARRISBURG, PA.

One of the most important problems facing many prepayment medical plans concerns the manner in which they shall cooperate with Blue Cross organizations. In approaching this problem, we must first of all recognize the more basic problem we are all trying to solve. That problem is to equalize the financial impact of sickness. It is generally agreed that the answer to this problem lies in the application of the insurance formula to the cost of medical care. There is considerable disagreement, however, about how such an insurance plan should be administered. Some people believe that a compulsory governmental plan is the answer. Others believe in the voluntary approach afforded by Blue Cross and medical prepayment plans.

In order to win the support of the public for such voluntary plans, it is essential that these plans do a good job without delay. No one should be deluded about the present success of these voluntary efforts. The December 1944 issue of *Fortune* magazine carries a feature article entitled "U. S. Medicine in Transition." One of the conclusions reached by the editorial board of *Fortune* is that "Blue Cross is popular and solid but its scope of benefits is so limited that it can contribute little to the extension of medical care required by the country." In many respects Blue Cross has done a remarkable job, but Blue Cross plans are only a partial answer to one small segment of the total problem. To date voluntary medical plans have provided an even less complete solution to another segment of the problem. The vast majority of people are not members of either plan, and the combined coverage of the two plans still leaves large areas in the field of medical care untouched.

The common goal of both Blue Cross and voluntary medical plans is to solve the basic problem more satisfactorily than any government plan. In order to accomplish this goal, Blue Cross and medical service plans must work harmoniously and effectively together. If these plans work independently, each will continue to attack only a small segment of the basic problem. They will also encounter such difficult administrative problems as dual payroll deductions, confused public relations and uneconomical duplication of effort. If these plans work at cross purposes, they will merely fertilize the soil in which the seeds of federalized medical care are being planted. Mutual cooperation, therefore, is essential to the optimum success of both plans—Blue Cross as well as medical.

Cooperation is a two way, give and take proposition. It requires adjustments on both sides and continued respect for the rights and privileges of both groups involved. In real cooperation there can be no attempt by either organization to dominate the affairs of the other.

In general, the relationship between Blue Cross and medical plans follows one of these four patterns:

A. *No coordination of activities.* Under this arrangement each plan operates independently of the other.

B. *Separate corporations and separate administrative staffs.* Under this arrangement Blue Cross contracts to perform certain functions for the medical plan—usually

publicity, sales promotion, collection of premiums and service to member groups. The medical plan handles its own claims, its relations with the medical profession and its general books of account. The relationship between the two corporations is that of independent contractors.

C. Separate corporations but identical administrative staffs. Under this arrangement medical service is administered completely by the Blue Cross plan. The medical plan exists in theory, but it has no personnel. The administrative staff of the Blue Cross plan serves also as the administrative staff of the medical plan.

D. One corporation. Under this arrangement medical service is included as part of Blue Cross coverage. The medical plan, as an independent organization, does not exist.

Although some of the earliest medical plans did not originally contemplate joint operation with Blue Cross, the advantages of mutual cooperation soon became apparent to all concerned. Consequently, all of the larger medical plans now cooperate with Blue Cross plans. In a few localities cooperation has reached the extreme of complete amalgamation. This is the case in Delaware, Chapel Hill, N. C., and Huntington, W. Va.

Most medical plans are coordinated with Blue Cross on the basis of arrangement B or arrangement C. The number of plans in each of these categories is about equally divided, but the number of subscribers covered by plans operating under arrangement B (separate corporations and separate administrative staffs) is approximately three times the number covered by all other plans combined.

There is practically no disagreement among those interested in either Blue Cross or medical plans with regard to the advantages of joint operation. The argument centers around the degree to which Blue Cross should manage the affairs of medical plans. In Delaware, for example, the medical profession apparently believes that only one corporation is necessary. In Colorado, Massachusetts, New York and a few other places there are two corporations but the profession has apparently agreed to sacrifice separate administrative identity and to relinquish all executive management to the Blue Cross staff. Even in California, Michigan, New Jersey and Pennsylvania—which have the most moderate type of cooperative arrangement—the medical plans have turned over to Blue Cross management the responsibility for certain of their important functions.

Since Blue Cross plans were in the field first and, as a consequence, had administrative organizations already set up, it was only natural that cooperation developed in the manner in which it did; namely, that Blue Cross organizations were engaged to perform certain services for medical plans. It would have been just as logical for medical plans to perform these services for Blue Cross had the order of precedence been reversed.

The important fact to note, however, is that under all three methods of cooperation every concession required has been made exclusively by the medical plans. In an effort to combat a fast moving social trend which threatens to engulf both these voluntary efforts, even the most conservative medical plans have willingly entrusted to Blue Cross management the important functions of public relations, sales, premium collection and service to member groups. Blue Cross, on the other hand, has relinquished none of its authority or responsibility; in fact, it has never been asked to do so. No

medical plan in our knowledge has ever proposed that it handle even the smallest fragment of Blue Cross activity.

Concession and compromise on the part of medical plans are desirable in order to achieve unified public relations, single payroll deductions and economy of operation. However, many thoughtful physicians are sincere in their belief that it is neither necessary nor desirable for medical plans to surrender their corporate existence (as required by arrangement D) or their separate administrative identity and all executive management (as required by arrangement C).

Medical leaders in the states of California, Michigan, New Jersey and Pennsylvania believe that cooperative arrangement B is the most desirable. Following are some of the more important reasons why they have reached this conclusion:

ARGUMENTS FOR ARRANGEMENT B (SEPARATE CORPORATIONS AND SEPARATE STAFFS)

1. It provides for unified public relations and thereby solves one of the basic problems of independent operation
2. It permits a single payroll deduction and thereby solves one of the most important practical difficulties of separate operation.
3. It promotes desired economy of operation through the use of a single sales force and the joint collection of premiums.
4. It allows for the assumption of active responsibility and authority by the medical organization in the operation of its own plan. This is a distinct advantage according to the conclusion of A. M. Simons and Nathan Sinai, as reported by the Committee on the Costs of Medical Care: "A comparative study of many health insurance systems seems to justify the conclusion that the evils of insurance decrease in proportion to the degree that responsibilities, with accompanying powers and duties, are intrusted to the medical professions."
5. This type of arrangement is in successful operation in the two oldest and largest medical plans in the country—California and Michigan.

The chief arguments against arrangement B, together with comments on these arguments, are as follows:

ARGUMENTS AGAINST ARRANGEMENT B

1. It is sometimes stated that in Michigan, which has the outstanding medical plan in the country, the two organizations are not actually operating as separate units in accord with the terms of their current joint operations agreement.

This statement has been categorically denied in recent communications received from officials of both plans in Michigan. The charge is a serious one, and—if true—it should be supported by evidence, none of which has been thus far produced.

2. It is said that the trend is away from arrangement B and in the direction of arrangement C—complete Blue Cross management of medical plan administration.

That assertion may be true, but it has no merit as an argument because trends can be either good or bad. There is, for example, a much more powerful trend toward a compulsory governmental plan for both hospitalization and medical care. If we are simply to follow trends, why not follow that one?

3. It is argued that arrangement B is not as economical as arrangement C.

This may be true to a small degree—perhaps 1 or 2 per cent. But real saving in the cost of administration occurs between arrangement A (independent operation) and arrangement B. Under arrangement B all impor-

tant functions which would otherwise have to be duplicated are administered by the Blue Cross plan. This includes publicity, sales promotion, collection of premiums and service to member groups, all jobs which would have to be done twice under independent operation. But that is not true with claims, each of which has to be processed only once no matter who does the job. There must be a medical director with an adequate staff to handle medical claims, whether this work is done by the medical plan or by the Blue Cross plan. To combine the two claim departments may effect some slight saving, but it would never reach major proportions.

4. Physicians, it is said, are not qualified to manage a business enterprise.

Modesty is commendable, and it is wise to acknowledge human limitations; but such an admission on the part of the medical profession would carry self abnegation to unwarranted depths. The American Medical Association, most of the state medical societies and even the larger county medical societies conduct many enterprises in which good business procedure is essential. Publication activities of these medical organizations—to mention only one feature of their work—involve millions of dollars annually; yet control of medical societies is vested in boards composed exclusively of physicians who discharge their responsibilities with success. The medical plans in California and Michigan are being operated successfully by physicians.

Blue Cross boards are composed of educators, contractors, hospital administrators, physicians, philanthropists, bankers, politicians, merchants and representatives of a hundred and one other fields of human endeavor. Executives of successful Blue Cross and medical plans have likewise come from many fields, including accounting, insurance, hospital administration, medical society work, the produce business, governmental service, the practice of medicine, sales, statistics and welfare work.

Are contractors or bankers or politicians or merchants any better qualified to determine the policies of medical plans than the medical profession?

There is probably not a Blue Cross board member in the country who could manage the statistical department of his own plan. All such boards must buy legal advice, executive ability, actuarial knowledge, statistical training and a host of other specialized skills. Boards of directors composed of physicians can buy all these things just as easily as boards composed of laymen. Physicians are not expected to do the job of executive management themselves.

5. The point is made that good business administration demands unified rather than dual authority.

Every one agrees that single authority is a fundamental of successful business administration. However, arrangement B provides for just that. Michigan Hospital Service, for instance, contracts with Michigan Medical Service to perform certain functions for the medical plan. Michigan Medical Service has no control over the employees of Michigan Hospital Service, which operates a clearcut, straight line organization headed by its executive director, who retains complete and exclusive authority with no interference whatever by the medical plan. The relationship between the two organizations is simply that of independent contractors. Real twin headed authority, which is admittedly unhealthy, exists only in arrangement C.

6. The fear is sometimes expressed that Blue Cross plans might jeopardize the good will of their subscribers if they act as the sales agency for medical service but do not also settle medical claims.

The best proof that this fear is unjustified lies in the success of Michigan Hospital Service, whose officers wrote under date of Dec. 8, 1944 that "there has been no difficulty with Michigan Hospital Service subscribers because it does not process and approve the claims of Michigan Medical Service."

This method of cooperation, in fact, has enabled Michigan Hospital Service to become the second largest Blue Cross plan in existence. It ranked third nationally in net enrolment gain for the third quarter of 1944. These facts not only dispel apprehension about arrangement B but, on the contrary, emphasize that it operates to the advantage of the Blue Cross plan.

There seems to be a tendency for most of the newly formed medical plans to follow cooperative arrangement C in their relationship with Blue Cross plans. Perhaps there are some advantages to this type of arrangement, but there are also insidious hazards involved which should be seriously considered. Following are the most important:

HAZARDS IN ARRANGEMENT C (TWO CORPORATIONS, ONE STAFF)

1. Arrangement C necessitates dual authority at the top, which is unanimously condemned.

Under this type of arrangement the chief executive is in charge of both corporations and is therefore obliged to report to two boards of directors. He and his staff must serve two masters, and this has never been accomplished to the satisfaction of all concerned. Such an arrangement may seem to work well for a brief period, but the test of time will reveal its inherent weaknesses.

2. In actual practice, if the interests of the two organizations do not exactly coincide, the executive and his staff will favor the dominant organization.

In the beginning this would put the medical plan at a disadvantage; later it might put the Blue Cross plan at a similar disadvantage. One condition is as unhealthy as the other, and neither should be permitted to develop.

3. This arrangement creates a situation under which the Blue Cross plan, which provides none of the funds and underwrites none of the losses for the medical plan, spends all of the money and manages all of the activities of the medical plan.

According to Jay C. Ketchum, executive director of Michigan Medical Service and former deputy insurance commissioner for the state of Michigan, such a condition would be intolerable to the medical plan. "Claim administration," he says, "must remain in each plan for its own subscribers."

4. Arrangement C puts the medical plan at the mercy of any weakness in the management of the Blue Cross plan because—with no active organization whatever of its own—it has no other choice but to rely with pathetic impotence on the hospital plan with which it is associated.

Blue Cross plans in general have done a good job, but neither their officials nor their staffs are immune to the weaknesses of other human beings. What opportunity would the board of directors of the medical plan have under this arrangement to correct an unsatisfactory condition in the Blue Cross method of administering medical activities, particularly if the two boards dis-

agreed? To make the attempt may bring the organizations into a headlong clash. Ultimately the medical plan would have to acquiesce for the obvious reason that it would have no alternative.

5. Arrangement C encourages the deterioration and ultimate dissolution of the medical plan.

This is true because arrangement C is based on the fallacious theory that an organization can remain strong and vigorous when stripped of all activity and responsibility. That is just as impossible with a business organization as it is with a physiologic organism. To be sure there will be a theoretically active board of directors for the medical plan; but the organization they represent will be teamed with a stronger one which shoulders all the burdens of both. In that rarefied atmosphere the members of the board of the medical plan will lose interest because of lack of responsibility. Their participation will gradually become more and more passive, and the medical plan itself will atrophy like a muscle from inactivity. The final result will be complete absorption by Blue Cross.

6. The gravest danger of arrangement C is its irreversible finality.

Theoretically any of the four arrangements can be tried experimentally and, if found unsatisfactory, discarded in favor of another method of coordination. Unfortunately, however, it does not work out this way in actual practice. Modifications in the direction of increased Blue Cross control can be made easily, but modifications in the other direction are difficult and, once large volume is achieved, virtually impossible.

In Michigan, for example, arrangement B is in effect. It would be a simple matter, administratively speaking, to change to arrangement C or even to arrangement D. Michigan Hospital Service could completely absorb Michigan Medical Service at a moment's notice. Blue Cross would simply take over the assets and equipment of the medical plan and continue to employ as many of the hundred-odd employees of Michigan Medical Service as were needed in the new setup.

To change from cooperative arrangement B to completely independent operation, however, is a different matter. Michigan Medical Service with three quarters of a million subscribers would be obliged to start from scratch in the matter of public relations, sales promotion and premium collection. That would be difficult. But the problem which would make the task impossible involves the securing of two payroll deductions where only one exists today.

The likelihood that the plans in Michigan will change in either direction seems remote. However, because of the hazards of arrangement C, many persons believe that medical plans operating on that basis will want to change to arrangement B at some future time. If that comes to pass after these plans have secured real volume, they will find that they have been traveling on a one way street. For example, assume that arrangement C was now in effect in Michigan. That means that the medical plan would exist on paper only, with no working personnel, no equipment, no administrative setup whatever, nothing but a board of directors. To effect a change from arrangement C to arrangement B, this board of directors would face the job of administering surgical and obstetric care to three quarters of a million persons. And they would have nothing to start with! Simply to state the problem is to prove that it could not be solved.

Arrangement B can be started as an experiment which, if proved unsatisfactory, can be changed to arrangement C or arrangement D at any time in the future. Arrangement C, however, virtually eliminates the possibility of changing in the opposite direction. To all practical purposes it involves final and irreversible action rather than experimentation. This condition should be clearly understood by everybody interested in medical service plans.

Arrangement C cannot long endure. Ultimately it must move in the direction of either arrangement B or arrangement D. Since large volume will eliminate the possibility of moving toward arrangement B, the only course open is complete amalgamation with Blue Cross. The choice, therefore, really lies between arrangement B and arrangement D, and this alternative should be realistically faced at the outset.

If it can be proved that Blue Cross should completely administer medical as well as hospital service, let us honestly admit that fact. Then let us take positive steps to disband medical plans in a forthright manner and cooperate with Blue Cross in an effort to add medical service to their coverage. If it is not proved that Blue Cross should completely administer medical service, then let us strive to maintain the independence of medical plans. That can be done only by having them continue to be organizations with real responsibilities. Under any other arrangement they will deteriorate. It would be a mistake for the medical profession to pave the way for the dissolution of medical plans by default.

Granted that there may be some merit to the arguments in favor of arrangement C (as there usually is in such differences of opinion), the fact remains that medical plans which desire arrangement B are asking nothing more of Blue Cross than the right to retain a little more responsibility for the conduct of their own affairs than some people think they should have. Medical plans are requesting no voice whatever in the management of Blue Cross activities. This fact, coupled with the knowledge that when a medical plan begins to cooperate with Blue Cross it can move in only one irreversible direction, points inevitably to arrangement B as the soundest and most equitable method of beginning to work together cooperatively. One may enter lightly on a course of action which involves no permanent commitment; but in areas of conduct which require irrevocable decisions, anything less than judicious consideration and temperate action is unworthy of mature minds.

The justification for this point of view will be recognized by all fair minded men, who can therefore be expected to regard the attitude of the medical profession with sympathetic understanding. Helpful cooperation should then follow as a natural result.

Blue Cross has been accused of attempting to dominate medical service plans. This accusation has been emphatically denied by Blue Cross officials. Whether or not it is justified remains to be seen. However, in justice to those who make such charges, it must be admitted that the trend has been toward increased control of medical plan activities by Blue Cross organizations.

If Blue Cross officials are sincere in their denial of this accusation and if they want to cooperate with medical plans in an effort to preserve the voluntary principle under which both organizations operate, they have the opportunity to prove their sincerity to all members of the medical profession. All they have to

do is to acknowledge that real cooperation is a two sided proposition which requires each contracting party to give as well as take in the readjustment process. Once this fact is acknowledged by all concerned, representatives of Blue Cross and medical plans can, by working together, solve the problem of coordination.

Arrangement B will work. In fact, it has been working for five years in the medical plan which has more subscribers than all other plans combined. Here is what the officers of the cooperating Blue Cross plan say about this arrangement in a communication dated Dec. 8, 1944: "Michigan Hospital Service would recommend very highly this type of cooperation to any Blue Cross plan."

TREATMENT OF STAPHYLOCOCCIC, PNEUMOCOCCIC, GONOCOCCIC AND OTHER INFECTIONS

WITH PENICILLIN

GONOCOCCIC INFECTIONS

Table 3 records the results of the penicillin treatment of 12 female patients with sulfonamide resistant gonorrhea, and 1 male patient with sulfonamide resistant gonococcic prostatitis and epididymitis. Before being given penicillin each of the female patients in this series was subjected to an intensive course of sulfadiazine therapy during which the blood concentration of the drug was maintained at a level of 7 to 20 mg. per hundred cubic centimeters. Only after the sulfonamide therapy had failed to cure the infection was penicillin treatment instituted. In all but 2 cases a total dosage of only 75,000 units or less was employed. All but 1 of the 12 female patients were followed in the hospital for a period of thirty days after treatment.¹¹ During this period only one questionable relapse was observed. The following case report illustrates the effectiveness of penicillin in the treatment of acute peritonitis caused by a sulfonamide resistant strain of gonococcus:

CASE 57.—History.—M. B., a woman aged 20 years, was exposed to a known case of syphilis approximately five months before admission to the hospital. Shortly thereafter she was told that her serologic test for syphilis was positive, and she received antisyphilitic treatment in a hospital near her home. Two months before entering the Barnes Hospital she was transferred to the Mid-West Medical Center, where she was found to have gonococcic urethritis and cervicitis. For the latter infection she was given 4 Gm. of sulfathiazole a day for five days. Since cervical cultures remained positive, she was later given 6 Gm. of sulfadiazine a day for five days. During this period she stole a supply of tablets and took an extra one for each one given by the nurse. In spite of the relatively large amounts of sulfadiazine ingested by the patient, gonococci continued to survive in the vaginal discharge. Further examination revealed a large inflamed cervix with profuse milky discharge issuing from the cervical os. There was bilateral parametrial tenderness. The blood Kahn test was negative. On admission

to the Barnes Hospital the patient was given a second course of sulfadiazine therapy during which the concentration of drug in the blood reached levels of 12 and 14 mg. per hundred cubic centimeters. Five days after the drug was discontinued the patient began to menstruate and suddenly developed severe lower abdominal pain, fever, pronounced rebound tenderness, muscle spasm and boardlike rigidity of the entire abdomen. Vaginal palpation caused severe pain. A diagnosis of gonococcic peritonitis was made, and the patient was given 20,000 units of penicillin intravenously, followed by two intramuscular injections of 20,000 units each at four hour intervals. Subjective improvement with complete disappearance of abdominal pain was noted four hours after the first injection, and on the following morning the patient felt completely well (fig. 8). She remained in the hospital for thirty days of observation, during which time repeated cervical smears and cultures failed to reveal the presence of gonococci.

Summary.—A woman aged 20 with gonococcic urethritis and cervicitis failed to respond to three courses of sulfonamide therapy. Shortly after the third course she developed acute gonococcic peritonitis, which responded promptly to 60,000 units of penicillin given over an eight hour period. Observation of the patient for a thirty day period did not reveal recurrence of the gonococcic infection.

MISCELLANEOUS INFECTIONS

Patients with various other infections were also treated with penicillin (table 4). Those with brucellosis (case 69), cryptococcic meningitis (case 70), histoplasmosis (case 71), ulcerative colitis (cases 20, 73 and 74) and actinomycosis (case 72) all failed to respond to treatment. Three patients with subacute bacterial endocarditis were treated with penicillin (patients 75, 76 and 77). The first died at the end of the first week of treatment. The other 2 relapsed soon after the completion of a first course of treatment but they were retreated and now show no evidence of recurrence more than two months later. The last of these 3 patients was a woman aged 26 whose bacterial endocarditis was first noted when she was six months pregnant. She was carried through the last three months of pregnancy on penicillin treatment, was delivered of a normal full term child and was treated for more than one month post partum. A clinical diagnosis of patent ductus arteriosus had been made, and surgical exploration of the chest was carried out but no patent ductus was found. The patient received a total of 15,850,000 units of penicillin. Three months after the discontinuance of therapy she still had no fever or symptoms and the blood culture remained negative. Six patients with brain abscess (patients 26, 82, 83, 84, 100 and 101) were treated with penicillin and all but 1 died. In the 1 case in which recovery occurred, diagnosis was made on clinical evidence alone without benefit of surgical exploration. Established suppurative infections of the lungs (cases 92, 93 and 94) showed little response to penicillin therapy with the exception of that seen in 1 patient with a postoperative lung abscess who recovered promptly following penicillin treatment and bronchoscopy. A single patient with meningococcic meningitis (patient 68) was treated with penicillin and made a rather remarkable recovery in spite of the fulminating character of the infection. The effectiveness of penicillin in meningococcic infection and its ineffectiveness in brucellosis are illustrated by the following case reports:

CASE 68.—History.—J. A., a man aged 30, entered the St. Louis Isolation Hospital,¹² having had an upper respiratory tract infection for seven days and severe headache for two days. Thirty-six hours before admission he noted aching of his back

11. The twelfth patient remained in the hospital for only six days.

12. This case is reported through the courtesy of Dr. R. W. Maxwell.

and legs, and twelve hours later his neck became stiff and he began to vomit. When first examined he was comatose, his temperature was 37.2 C. (98.9 F.) and there was pronounced stiffness of his neck. Many small petechiae were seen over the neck, thighs, legs and feet. The Kernig sign was positive, and a blood count revealed a leukocytosis of 28,000. The spinal fluid was turbid and contained many gram negative intracellular diplococci later identified by culture as meningococci. The patient was immediately given sodium sulfamerazine subcutaneously, and the concentration of drug in the blood reached a level of 17.7 mg. per hundred cubic centimeters. In spite of this intensive sulfonamide chemotherapy the patient remained in coma, and culture of the spinal fluid drawn after forty-eight hours of treatment still revealed many meningococci. Because of the failure of the patient to respond to sulfamerazine, this form of treatment was discontinued and penicillin treatment was begun. The penicillin was administered by the intravenous, intrathecal and intracisternal routes; within twenty-four hours the patient regained consciousness, and on the following day he was able to take food by mouth. After three days of penicillin treatment the fever subsided and the patient made an uneventful recovery (fig. 9).

Summary.—A man aged 30 with meningococcal meningitis of five days' duration failed to respond to forty-eight hours of

gram positive cocci and gram negative diplococci. The therapeutic response observed in various forms of staphylococcal infection, severe pneumococcal disease (including meningitis), sulfonamide resistant gonorrhea and fulminating meningococcal meningitis is in agreement with results previously reported by British investigators¹¹ and by the Committee on Chemotherapy and Other Agents of the National Research Council.¹ Limited evidence is also advanced that penicillin has little effect in the treatment of brucellosis, histoplasmosis, cryptococcal meningitis and ulcerative colitis. Results in chronic osteomyelitis and brain abscess have been somewhat equivocal and, on the whole, disappointing, but further trial of penicillin in the treatment of these conditions is indicated. Although at present inconclusive, the results in 2 cases of subacute bacterial endocarditis have been encouraging.

Among the 20 patients with severe staphylococcal infection treated with penicillin, only 3 died. Sixteen of these patients were suffering from bacteremia when admitted to the hospital; the other 4 exhibited clinical signs of metastatic staphylococcal lesions indicating

TABLE 3—Gonococcal Infections

Case No.	Age	Sex	Diagnosis	Duration of Disease, Days	Penicillin Treatment			Other Specific Treatment	Results	Comment
					Days of Therapy	Total Dosage, Units × 1,000,000	Routes of Administration			
55	23	♀	Urethritis; cervicitis; salpingitis	130	1	0.060	IV, IM	None	R

65	25	♀	Urethritis; cervicitis; salpingitis	35	1	0.075	IV, IM	None	R	
66	29	♀	Urethritis; cervicitis; incomplete abortion	65	2	0.300	IV, IM	Dilation and curettage	R	Two positive smears and negative cultures after 75,000 O U; negative for 30 days after 225,000 O U.
67	25	♂	Urethritis; prostatitis; epididymitis	57	5	1.200	IV	None	R	

intensive sulfonamide chemotherapy. At the end of this period he was placed on penicillin treatment and recovered promptly.

CASE 69.—History.—L. W., a man aged 20, a butcher in a large packing house in St. Louis, noted malaise, fever, night sweats and increasing weakness twenty-five days before coming to the hospital. During the next two weeks these symptoms persisted and he lost 24 pounds (11 Kg.) in weight. Physical examination at the hospital revealed a temperature of 39 C. (102.2 F.), evidence of recent weight loss, moderate hepatomegaly, a palpable spleen and generalized lymphadenopathy. The white blood cell count was 4,200, with 60 per cent lymphocytes. A brucella organism was grown from the blood, and the patient's serum agglutinated the brucella antigen in a dilution of 1 to 2,560. The patient was treated intensively for one week with penicillin. Not only was the fever uninfluenced by the treatment but the blood cultures also remained consistently positive (fig. 10).

Summary.—Intensive penicillin treatment failed to influence the course of a severe brucella infection. Repeated blood cultures remained positive both during and after therapy.¹³

COMMENT

The results of the present study indicate that penicillin is a highly effective chemotherapeutic agent in the treatment of a variety of bacterial infections caused by

previous invasion of the blood stream. One of the patients who recovered was thought to have cavernous sinus thrombosis (patient 21). Although recoveries from this type of infection have been reported, they are certainly uncommon.¹⁵ The 3 fatal cases included a woman aged 33 with staphylococcal bacterial endocarditis, who died from rupture of a metastatic brain abscess, a youth aged 16 with staphylococcal furunculosis of the face who entered the hospital for treatment only after having developed metastatic pneumonia, cavernous sinus thrombosis and staphylococcal pericarditis and a woman aged 32 with ulcerative colitis who died from a massive intestinal hemorrhage. Recovery could hardly have been expected in any 1 of these 3 cases.

The significance of these results becomes apparent when they are compared with those reported by Skinner and Keefer¹⁶ in a series of 122 cases of staphylococcal bacteremia treated before the advent of penicillin. Among this large number of patients only 22 recovered.

* Culture not taken.

tinued or the dose was reduced. In 1 case a residual lateral sinus thrombosis was found when a second surgical operation was performed (case 37). This experience suggests that demonstrable infected foci should be drained surgically and that penicillin treatment should be continued for at least a week or more after the clinical manifestations of meningitis have subsided. It is of interest that 5 of the 9 patients treated in the present study were subjected to mastoidectomy. The relatively high recovery rate observed may be related to the fact that the original focus responsible for the meningitis was eradicated surgically whenever possible.

Our experience with penicillin in the treatment of pneumococcal infections of the lungs is far too limited to be significant. Four patients with pneumococcal pneumonia responded to penicillin therapy, while 2 died. One of the latter apparently succumbed to uremia following a reaction to sulfonamide treatment, and the other was treated less than twenty-four hours before death. In 2 cases of pneumococcal empyema cultures of pleural fluid showed no growth soon after intrapleural administration of penicillin. Fever and leukocytosis, however, persisted in each case so that eventually it was necessary to perform a thoracotomy to evacuate the pus. It is possible that surgical operation could have been avoided even in these cases if the intrapleural injections of penicillin had been continued over a longer time.

Several investigators have already demonstrated conclusively that sulfonamide resistant gonorrhea in the male can be rapidly cured by penicillin therapy.¹⁹ Two comparable studies of female patients have been reported.²⁰ The use of penicillin in the treatment of gonococcal infections in the present investigation was limited in all but 1 case to women. Twelve female patients were treated with penicillin only after intensive sulfonamide treatment had failed to eradicate the infection. All but 1 patient responded promptly to a relatively small dose of penicillin (60,000 to 75,000 units) and the latter patient was promptly cured when retreated with a larger dose of the drug.

No untoward reactions to penicillin were noted in the present study. There was 1 questionable instance of urticaria, and a few patients complained of burning at the site of the intramuscular injection. Although thrombosis at the site of the intravenous injection was occasionally observed, it was thought in each case to be due to an indwelling needle rather than to the solution of penicillin. Persistent pleocytosis in the presence of negative spinal fluid cultures was seen in 1 patient with pneumococcal meningitis who was given penicillin intrathecally every day for a week in doses of 10,000 to 20,000 units. As soon as the intrathecal injections were discontinued, the cell count of the spinal fluid fell definitely. The virtual absence of toxic reactions observed in the present study confirms the generally accepted

opinion that penicillin is the least toxic effective therapeutic agent yet developed for the treatment of bacterial infections.

SUMMARY

1. Penicillin was used in the treatment of 103 patients suffering from various forms of bacterial infections.

2. The drug was administered systemically by both the intravenous and the intramuscular route. Systemic treatment was combined with local penicillin therapy whenever indicated, as in the treatment of surgical wounds, intrapleural and intrapericardial infections and meningitis.

3. Twenty patients with severe generalized staphylococcal infection, 16 of whom had bacteremia, were treated with penicillin. Only 3 died. Of the 11 patients in this group exhibiting metastatic staphylococcal pneumonia, only 1 failed to survive.

4. Patients with acute local infections due to the staphylococcus responded promptly to penicillin treatment.

5. Chronic infections due to *Staphylococcus aureus* responded less dramatically. Patients with chronic osteomyelitis showed temporary improvement, but in most instances there was eventually a recurrence of the infection.

6. Nine patients with pneumococcal meningitis were treated with penicillin, and all but 1 recovered. Mastoidectomy was performed in 5 of the 9 cases. The importance of continuing treatment for some time after the signs of meningitis have subsided was emphasized by the occurrence of relapse in 3 cases. Each of the 3 patients suffering relapse responded promptly to further therapy and eventually recovered.

7. Penicillin was found to be effective in the treatment of pneumococcal pneumonia but failed to cure pneumococcal empyema in 2 patients until after surgical drainage was instituted.

8. Twelve women with sulfonamide resistant gonorrhea were promptly cured with small doses of penicillin. Each patient was observed in the hospital for thirty days after the termination of treatment and only one questionable relapse occurred.

9. One patient with fulminating meningococcal meningitis responded dramatically to penicillin after forty-eight hours of treatment with sulfamerazine had apparently failed to influence the infection.

10. Three patients with acute bacterial endocarditis due to *Staphylococcus aureus* were treated with penicillin. One patient died; the other 2 are apparently well after two months and four months respectively. Three patients with subacute bacterial endocarditis due to *Streptococcus viridans* were treated. The first died; the other 2 relapsed soon after the completion of a first course of treatment but were retreated and now show no evidence of recurrence more than two months later.

11. No beneficial effects were noted in the treatment of brucellosis, cryptococcal meningitis, histoplasmosis and chronic ulcerative colitis.

12. The use of penicillin did not appear to eliminate the necessity for surgical drainage in certain cases of established pyogenic infections, but it was thought in some instances to lessen the risk of surgical operation.

13. No significant toxic reactions were observed.

Clinical Notes, Suggestions and New Instruments

CONGENITAL RECTOPERINEAL FISTULA ASSOCIATED WITH CONGENITAL ABSENCE OF THE VAGINA

G. SYDNEY McCLELLAN, M.D., AND EDWIN L. WILLIAMS, M.D.
NASHVILLE, TENN.

There are numerous reports of congenital anomalies of the anus and rectum including the writings of Berman,¹ Chandler,² Crowell and Dulin³ and David.⁴ Reports of congenital absence of the vagina include publications by Baldwin,⁵ Wharton⁶ and Frank.⁷

Little has been written, however, concerning a combination of rectal and vaginal deformities occurring in the same individual. This is doubtless due to the scarcity of clinical material. It is therefore our purpose in this paper to present a case of multiple congenital anomalies appearing in the same individual and to describe in some detail the operative procedures performed for their correction.

Fig. 1.—Vulva and perineum as first seen: A, urethra; B, vaginal dimple; C, perineal anus; D, sphincter ani.

revealed a normal clitoris, labia majora and labia minora. There was a depression 2 cm. in depth where the vagina normally is located. The anal orifice was situated 1.5 cm. below the rudimentary introitus. Two fingers readily passed into this opening, and there was no evidence of a sphincter muscle. Approximately 1.5 cm. below the anus there was a small dimple with radial skin folds resembling somewhat the skin folds of the normal

SUMMARY OF CASE

A white girl aged 17 years, single, was admitted to the Vanderbilt University Hospital outpatient department Sept. 9, 1943, complaining of amenorrhea. She reported that for the previous eighteen months she had dull aching pains in the lower part of the abdomen lasting one or two days and occurring at intervals of one to two months. She stated that she expected to menstruate at these times but had never had a vaginal flow.

The only other complaint was intermittent incontinence of feces.

A general physical examination revealed that the patient was well developed and had normal secondary sex characteristics. Mammary development was compatible with her age. Axillary and pubic hair was normal in amount and distribution. Examination of the genitalia

anus. This dimple was surrounded by a subcutaneous firm structure which was apparently an anal sphincter. The patient was able to contract the muscle voluntarily on instruction.

It was evident that she had a congenital absence of the vagina and an ectopic anus.

Fig. 2.—Vulva and perineum after transplantation of rectum.

Examination by rectum did not reveal the presence of internal genitalia, although the apparent presence of ovarian tissue was exemplified by her well developed secondary sex characteristics.

Fig. 3.—Vulva and perineum after final operation. The artificial vagina is distended with a glass dilator.

7. Frank, R. T.: Evaluation of Treatment for Absent Vagina, *J. Mount Sinai Hosp.* 7: 259-262 (Jan.) 1941.

On admission of the patient to the Vanderbilt University Hospital several diagnostic studies were made. A pneumoperitoneum followed by x-rays revealed no definite pelvic organs. An abdominal film revealed an anomaly of the lumbosacral

region with articulation of the right transverse process of the fifth lumbar vertebra with the sacrum. Intravenous pyelograms showed both kidneys functioning well, with rotation and slight hydronephrosis on the right side. Barium injected into the rectum was seen about 2 cm. from the anal dimple. There was a considerable distance, therefore, between the rectum and the anal sphincter, and not merely a thin septum.

On October 11 a plastic procedure was performed under nitrous oxide and ether anesthesia. After preliminary cleansing, the tissues about the ectopic anal orifice were infiltrated with saline solution to which epinephrine had been added to facilitate dissection. A circular incision was then made around the opening at the mucocutaneous junction. The lower 8 cm. of the rectum was freed by means of sharp and blunt dissection. Adequate mobility of the rectum was thereby obtained. The skin over the anal dimple was removed by circular excision, and a canal was made through the perineum. This canal as well as the sphincter ani muscle surrounding it was then dilated until it admitted two fingers readily. The mobilized rectum was then threaded through this canal and anchored in place by multiple interrupted fine cotton sutures. The mucosa of the rectum was then sutured to the skin by radially placed cotton sutures. Finally the perineal body was repaired by the procedure usually carried out in a routine perineorrhaphy, the levator ani muscle having been plicated in the midline. The postoperative course was relatively uneventful. The incision healed by first intention with very little discomfort. By the fifth postoperative day the patient was able to have a normal bowel movement with little distress. It was necessary to educate her in regard to sphincter control. She received succinylsulfathiazole in doses of 0.25 Gm. per kilogram of body weight every twenty-four hours for six days prior to operation and for five days afterward. We are convinced that the use of this drug materially reduces the incidence of postoperative infection in surgery of the rectum.⁸

The patient was readmitted to the hospital five months later. At this time the anal sphincter control was still complete and her general condition was good.

On May 13, 1944, under nitrous oxide and ether anesthesia a transverse incision was made in the apex of the vaginal dimple. A cavity was then created by means of sharp and blunt dissection between the urethra and the rectum extending back to the peritoneum of the cul-de-sac of Douglas. Examination revealed no evidence of a cervix or uterine fundus. Little bleeding occurred. A 10 by 4 cm. cottonwood vaginal plug covered by rubber tissue was then placed in the newly created vagina and an indwelling catheter left in situ.

Six hours after operation the patient spontaneously expelled the wooden plug. She was again anesthetized and the cavity examined. Considerable bleeding occurred and it seemed advisable to pack the cavity and to secure hemostasis before the obturator was reapplied. After sixty hours it was reinserted and left in place for three weeks. A considerable amount of purulent drainage occurred about the plug, and the patient developed a mild cystitis. The infection responded promptly following administration of sulfadiazine. When the plug was removed at the end of three weeks, three fourths of the newly created vagina was epithelized.

The floor of the urethra near the meatus was destroyed as a result of pressure of the cottonwood plug. Nevertheless the patient had complete urinary control. A large glass vaginal dilator was left in the vagina almost constantly during the ten days during which she remained in the hospital. At the time of dismissal a completely epithelized vagina extending back to the cul-de-sac and 3.5 cm. in diameter was present. There had been no tendency to contracture. She was instructed to use the dilator for the greater part of each day for at least six more weeks.

CONCLUSIONS

In a patient presenting a combination of congenital anomalies, the method for eradicating the perineal anus and establishing

the normal anatomic relationship of the sphincter muscle to the anal orifice was completely satisfactory.

The use of the Wharton operation in the production of an artificial vagina seems a safe and relatively simple procedure. This method eliminates the dangers inherent in the more complicated operations.

Council on Foods and Nutrition

The Council has authorized the following report for publication.

GEORGE K. ANDERSON, M.D., Secretary.

THE ADDITION OF SYNTHETIC VITAMINS TO CONFECTIONERY

It is well known that several vitamins can now be manufactured on a huge industrial scale. This has made possible the current enrichment program by which wheat flour and bread are made the carriers of such important dietary factors as thiamine, riboflavin and niacin. It has also precipitated much discussion concerning the limits to which such addition of vitamins to foods should be carried. This discussion has been summarized elsewhere and therefore need not be reviewed in detail here.¹ Let it suffice to point out that at this date the opinions of this Council, the Food and Nutrition Board of the National Research Council and the Food and Drug Administration of the federal government have crystallized, so to speak, in favor of the appropriate enrichment of flour and bread (and perhaps other cereal products) with several factors and the fortification of milk with vitamin D, of table fats with vitamin A and of table salt with iodine. To what extent other additions will finally acquire widespread acceptance and then official approval only time and the accumulation of new data can determine.

Sugar, candy and sweetened carbonated beverages present another problem. Evidence can be cited in support of the view that the consumption by the American people of such a highly purified carbohydrate as cane sugar is so high as to be of some public health concern. The nutritional aspects of this problem have already been discussed by this council² and therefore need no extended comment here. It is pertinent, however, to point out that in its resolution on the general problem of the addition of vitamins and minerals to foods the Food and Nutrition Board of the National Research Council used in item 7 of the resolution the following words: "7. That, specifically, the Committee opposes the addition of synthetic vitamins to carbonated beverages and confectionery."

A product called Vi-Chocolin has been submitted to the Council for possible acceptance. This product consists of a mixture of such customary candy ingredients as cane sugar, vegetable lecithin, chocolate flavor and vanillin. Vitamins are added from other sources to provide each bar with the minimum daily adult requirements of the several vitamins for which minimum requirements are stated, in amounts as follows:

Vitamin A.....	4,000 U. S. P. units
Vitamin B ₁ (thiamine).....	1 mg.
Vitamin B ₂ (riboflavin).....	2 mg.
Vitamin C (ascorbic acid).....	30 mg.
Vitamin D (viosterol).....	400 U. S. P. units

It is evident that Vi-Chocolin is essentially a multivitamin chocolate coated candy bar, offered ostensibly as a specialty product of high nutritive value and of some use in medicine, but in reality intended for promotion to the public as a general purpose confection, a vitaminized candy. Vi-Chocolin therefore falls in the class of products which do not conform to the principles followed by the Council in dealing with enriched or fortified foods and therefore cannot be considered for the Seal.

CANCER OF THE CERVIX

In a review of cancer of the cervix Block¹ emphasizes that the best results in the treatment of the disease are obtained when it is diagnosed in its early stage. Most authorities agree that the absolute diagnosis of cervical cancer must depend on the microscopic examination, usually of a biopsy specimen. The iodine test of Schiller is useful in determining the suspicious areas in the cervix which should be subjected to biopsy. This test is based on the fact that the upper layers of the normal epithelium of the portio and the vagina contain rich masses of glycogen, which disappear when the epithelium becomes cornified or changed by cancer. In the normal living tissue the glycogen of the upper layers is stained a deep mahogany brown in a few seconds by Lugol's solution. A superficial area of early cancer, being devoid of glycogen, does not receive the stain and stands out startlingly white or pink against the deeply colored background of normal tissue. The test is completely reliable when it is clinically negative, that is, when all the tissues take the stain; therefore the test is specific in the absence of cancer. However, Block points out that the test is of little or no value in the presence of ulceration, erosion or chronic cervicitis.

Novak considers both the test and the use of the colposcope as of rather limited value. Neither procedure is of the kind which can be expected to achieve adoption by the general profession. The chief value of the Schiller test is to indicate the proper points for biopsy, though in a great majority of these cases, as pointed out by Block, the suspicious areas are apparent enough, sometimes pathetically so.

The study of vaginal smears as a means of early diagnosis of cervical or uterine cancer was advocated by Papanicolaou.² Cervical cancer is revealed in vaginal smears by the appearance of characteristic cells derived from the superficial layers of the tumor, which undergo

continual desquamation. These cells show great variety of form and size, much greater than that seen in sections of the tumor. The most characteristic feature of the abnormal cells is the atypical form and structure of their nuclei and vacuolization of the cytoplasm. A commonly found, characteristic cell type is an extremely elongated one resembling a smooth muscle fiber. Erythrocytes are generally found in large numbers. Block warns, however, that a positive diagnosis from a vaginal smear does not indicate immediate radical intervention or irradiation but rather that confirmatory biopsies of the cervix or endometrium should be performed.

Meigs and Jaffe have found in their analysis of the survival rates of patients undergoing irradiation that most of the deaths occur in the first two years and that most patients without obvious disease at the end of two years have a good chance for recovery. They conclude that it is only necessary to follow the cases for three years following treatment, and then by deducting 15 per cent the five year end results can be predicted. Therefore it is unnecessary to wait for five years following treatment before reporting a group of cases or to change a method of treatment. Kimbrough and Tompkins found that 23.3 per cent of the patients survived five or more years and that 18.7 per cent of the original group lived more than ten years after treatment.

One could cite numerous statistics favoring either radiotherapy or operation. Each method has its advantages as well as disadvantages. While the application of radium is a comparatively simple procedure many complications may occur. Most important is infection developing during the process of irradiation, the 2 per cent mortality charged against this procedure being due almost exclusively to the activation of hemolytic streptococci. The Ruge-Philipp test is of considerable value in avoiding this dangerous complication. Formidable complications may arise from irradiation injury to the intestine ranging from simple acute proctosigmoiditis to severe ulcerations of the bowel, leading in a small percentage of cases to perforation into the peritoneal cavity, causing peritonitis, into the vagina, producing rectovaginal fistulas, or into the perirectal tissues, giving rise to ischio-rectal abscesses. Colostomy is frequently necessary, especially if stenosis, hemorrhage or severe pain is a prominent symptom.

According to Block there is a tendency toward the resumption of operative treatment. In Bonney's series of 500 Wertheim operations the operative mortality rate was 14 per cent and was largely due to shock. In about 40 per cent of the cases the regional lymph nodes were involved, and in these the five year cure rate was only 23 per cent, as opposed to the cases free from lymph node involvement, in which the cure rate reached 58 per cent. The operative mortality was only 10 per cent in the lymph node free cases as against 20 per cent for

2. Vaginal Smears and Carcinoma of the Uterus, editorial, *J. A. M. A.* 124:1136 (April 15) 1944.

the lymph node involved group. Meigs gives five reasons why he has resumed the operative treatment of cervical cancer: 1. If the cervix has been removed there is no chance for a recurrence in it. 2. If the cervix has been removed, no cervical cancer can regrow in it as a recurrence. 3. Certain cancers of the cervix are radiation resistant. 4. There will be less damage to the bowel. 5. From the work of Bonney and Taussig it is obvious that patients with lymph node metastases can be cured by surgery. In some instances it is not possible to cure with radiation cancer in lymph nodes deep in the pelvis. The surgery must be limited to certain types of patients; ideally they should be thin, young and in good health and have an early growth.

The most significant complications of operative therapy are difficulties with the urinary tract. Cystitis, dilated ureters and hydronephroses are the rule after operation. In about 5 per cent of the cases urinary fistulas develop, which in all cases mean ultimate nephrectomy.

The experience of the patients who have had both methods of treatment has always been that the surgery was much easier to tolerate than the radiation. For over ten years Taussig has practiced the removal of the iliac lymph nodes in addition to irradiation of the primary tumor in group 2 cancer of the cervix and has done 175 of these operations. The percentage of five year survival in his series was over 15 per cent better in patients who had the additional procedure of the removal of iliac lymph nodes.

MALNUTRITIONAL IMMUNITY TO VIRUS DISEASES

In 1942 Foster and her associates¹ of the Department of Pediatrics, University of Pennsylvania, found that a deficiency of thiamine increases the normal resistance of mice to inoculations of the virus of poliomyelitis. The incubation period is shorter and the incidence of paralysis and death rate are much less than in control mice maintained at the optimum level of thiamine. They subsequently found that a similar increase in antiviral resistance resulted from a mere restriction of food intake or from a restriction in the carbohydrate fraction only while maintaining the normal intake of all other components.² At about the same time similar findings were reported by Rasmussen and his colleagues³ of the University of Wisconsin, who found that the decrease in susceptibility to poliomyelitis noted in mice on diets of restricted caloric value is less accentuated than that observed in mice which are deficient in thiamine. The malnutritional immunity was

demonstrated with both the Theiler's virus and the Lansing strain of poliomyelitis.

On account of the wartime interest in nutritional deficiencies, Foster and her group⁴ attempted a careful confirmation of the reported relative immunologic effects of vitamin B₁ deficiency and restricted food intake. They used carefully paired litter mates inoculated intracerebrally with the same dose of the Lansing virus. Two hundred mice were used in their titrations. These were divided into four groups of 50 mice each, the 4 animals from each litter being of the same sex. One group of 50 mice was fed ad libitum a restricted diet containing as little as 30 to 40 micrograms of thiamine per hundred grams. A second group was given an adequate diet containing 100 micrograms of thiamine per hundred grams, the amount of food eaten from day to day by this group being restricted to the daily food intake of group 1. In other groups the caloric intake was restricted without reduction in the intake of thiamine or other essential factors.

In all cases the onset of symptoms and deaths from paralysis occurred earlier in the adequately fed control group than with the deficiency animals. For example, by the eleventh day eighteen deaths occurred in the adequately fed group while there was but one death in the thiamine deficient group and but five deaths in the group with restricted caloric intake. Similar differences were recorded till the end of the experiment (twenty-eight days).

As previously reported by Rasmussen, a slightly greater number of deaths occurred in the low caloric group than with the thiamine deficient animals. Vitamin B₁ deficiency therefore apparently furnished a greater increase in normal antiviral resistance than that afforded by restricted food intake. Rasmussen also found that if thiamine deficient survivors are subsequently given adequate thiamine they often became paralyzed after a prolonged incubation period. This also was confirmed.

Malnutritional immunity is not limited to the poliomyelitis virus. As early as 1911 it was noted that undernourished chickens are practically immune to the Rous sarcoma virus.⁵ Subsequently it was found that diets restricted in such essential components as proteins, vitamins, minerals or fats inhibit the formation of both spontaneous and induced tumors in mice.⁶ Rabbits on a starvation diet are more resistant to vaccinia virus than adequately fed controls.⁷ Probably, therefore, malnutritional immunity is a phenomenon applicable to a wide range (possibly to all) virus diseases.

No adequate theory has thus far been developed to account for this apparent paradox: a malnutritional immunity to virus diseases coupled with a hyper-susceptibility to bacterial infections.

Current Comment

PEPTIC ULCERATION IN GASTRIC CARCINOMA

Ulceration apparently of peptic nature is not infrequent in gastric carcinoma.¹ At times such ulceration may present many features characteristic of simple ulcer, including reparative processes. Carefully studied cases of this nature have been reported recently by Eusterman,² Palmer and Humphreys³ and others. In each of Eusterman's 5 cases a small carcinoma, roentgenologically indistinguishable from simple ulcer, apparently healed completely under intensive medical treatment. The 4 cases described in detail by Palmer and Humphreys simulated simple ulcer in many respects at the same time as they presented diagnostic signs of carcinoma. In these cases the ulcers had the morphologic characteristics of simple ulcer with more or less well defined repair of the defects and carcinomatous infiltration of the walls. In none of these cases was there definite clinical evidence of preexisting simple ulcer. The cases mentioned illustrate difficulties in the way of prompt differentiation of simple and carcinomatous gastric ulcer. As emphasized by Palmer and Humphreys there appears to be "a mechanism by which the clinical symptoms, the roentgen evidence and the gastroscopic evidence of a gastric neoplasm may all disappear." The possibility must be kept in mind that under certain circumstances gastric carcinoma may respond so favorably to treatment that its true nature is not suspected as early as it should be.

BRITISH EXPERIENCE IN THE TREATMENT OF HYPERTHYROIDISM WITH THIOURACIL

Nussey¹ treated 27 unselected cases of hyperthyroidism with thiouracil for three weeks to twelve months. The results were favorable in all the cases save 1 of long standing. In the light of present experience Nussey regards it a safe working rule to give 0.2 Gm. of thiouracil three times daily for three to five weeks, when the amount should be reduced gradually and maintained at the lowest level compatible with the patient's well being. He urges that all patients so treated be kept under adequate supervision, also that all patients suffering from hyperthyroidism be treated with thiouracil. As it was as recently as in 1943 that Astwood² made the first clinical trial with thiouracil, it is not yet possible to tell whether a medical treatment of hyperthyroidism has been introduced that will replace the surgical. Fortunately, a safe basis seems to have been established for continued observations on the curative action of thiouracil.

INSULIN SHOCK THERAPY

The aim of the study¹ by the Temporary Commission on State Hospital Problems was to evaluate the effectiveness of insulin shock therapy in the treatment of patients with dementia precox. Of 2,004 studied, 1,128 were treated with insulin at Brooklyn State Hospital between Jan. 1, 1937 and June 30, 1942. The remaining 876, admitted to other Metropolitan State Hospitals during the same period, who did not receive any form of shock therapy but were as nearly comparable as possible with the insulin treated patients, were used as a control group. The criteria used for measuring the effectiveness of insulin shock therapy were the subsequent ability of patients to leave the hospital and return to their homes, the length of hospital stay before leaving, the length of time patients were able to remain at home and the extent to which they were restored to usefulness. The study showed that, as a group, the insulin treated patients did better in all respects than the nontreated patients. Thus 79.5 per cent of the insulin treated patients were able to leave the hospital as against 58.8 per cent of the nontreated group. The insulin treated patients had a consistently larger proportion able to leave the hospital than the nontreated patients. The difference was especially evident among the paranoics, 79.4 per cent as against 59.0 per cent. Among the insulin treated patients the hospitalization period prior to release was 3.8 months shorter per patient than among the nontreated. Among the patients with subsequent hospitalization the insulin treated patients spent an average of two months more at home than in the hospital, while the nontreated patients spent seven and one-half months more in the hospital than at home, constituting a saving of nine and one-half months of hospitalization per insulin treated patient. At the end of this study, between five and one-half years and six months after release of all the insulin treated patients 58.9 per cent were at home as against 44.0 per cent of the nontreated group. There was a consistently larger proportion of insulin treated patients in the higher levels of usefulness. A larger proportion of insulin treated patients returned to gainful employment as compared with the nontreated group, 71.1 per cent and 60.6 per cent respectively. The insulin treated group had a consistently larger proportion of patients who were doing well and as well as or better than they did before their illness, regardless of the time which elapsed between their release and the date of study. Insulin treatment has effected a saving of approximately 286,695 days of hospital care, a saving of approximately \$80,274.60 in cost of food and clothing and substantial, though undetermined, saving in maintenance costs and a still larger saving ultimately in construction costs. The determination that the highest percentage of improvement occurred among those in whom the illness was of short duration might be utilized in achieving even better results with insulin therapy if a technic could be established that would more certainly identify patients in the early stages of the illness than is now possible.

MEDICINE AND THE WAR

ARMY

CONVALESCENT SOLDIERS GIVEN PRETECHNICAL TRAINING

The War Department recently announced that pretechnical training in the arts and trades will be offered by the Quartermaster Corps as part of the conditioning of soldiers in convalescent hospitals. The courses will include canvas and leather work, sewing machine operation, clothing and textile repair, electrical work, topographic drawing, warehousing and utility repair. The training will be part of the current Army Medical Department program to recondition hospitalized soldiers for a return to service or for reentry into civilian life. The program also includes physical and educational reconditioning, occupational therapy and recreation. According to the Office of the Surgeon General, the program has resulted in a sharp decrease in army discharges due to disability. Approximately 12,000 men are being sent back to full duty each week, and the time of hospitalization has been reduced as much as one third.

ARMY APPOINTS RECRUITING COORDINATOR

The War Department recently announced the appointment of Miss Evelyn Blewett as civilian consultant to Major General Norman T. Kirk, Surgeon General of the Army, on the Army Nurse procurement and public relations program. Miss Blewett, who has handled such successful campaigns as the Wave Recruiting Campaign for the Navy and the "Food Fights for Freedom" program, will coordinate the procurement program with such other agencies as the Office of War Information, the Red Cross, the National Nursing Council for War Service, the Army's Recruiting Publicity Bureau, and the War Manpower Commission. She will continue to act as staff manager for the War Advertising Council in this emergency campaign.

DEAFNESS AMONG SOLDIERS

Cases of deafness among soldiers which were not detected at their induction are now being detected through the modern scientific methods in use by the Army Medical Department. Those with heretofore undetected deafness as well as those with service incurred deafness are being rehabilitated at Deshon General Hospital, Butler, Pa., Hoff General Hospital, Santa Barbara, Calif., and Bordon General Hospital, Chickasha, Okla. To provide hearing aid sooner for the deaf, earpieces to which the aid may be fastened are now being manufactured in the three hospitals, in this way overcoming the delay incident to packing and transmitting to manufacturers the cast for the earpieces, as well as for their return by mail.

COLONEL SIGAFOOS APPOINTED DEPUTY DIRECTOR

Lieut. Col. Rolland B. Sigafoos, formerly of Tacoma, Wash., who was recently awarded the Legion of Merit (*THE JOURNAL*, January 27, p. 225), has been appointed deputy director of the Training Division, Operations Service, Office of the Surgeon General. Colonel Sigafoos replaces Lieut. Col. Charles H. Moseley, assigned overseas.

ARMY HOSPITALS CONSOLIDATE

AAF Regional Station Hospital No. 1, consisting of the Casa Loma Hotel and Miami Biltmore Hotel, Coral Gables, Fla., and the AAF Convalescent Hospital, Miami Beach, Fla., have been consolidated and designated Army Air Forces Regional and Convalescent Hospital, Miami Area, Miami Beach, Fla.

ARMY AWARDS AND COMMENDATIONS

Captain Bradley C. Brownson

The Air Medal was recently awarded to Capt. Bradley C. Brownson, former fellow in surgery in the Mayo Foundation, for "meritorious achievement while participating in aerial flight during the period Jan. 17, 1944 to April 6, 1944." The citation read, in part, "In order that he might better acquaint himself with the special problems of the combat crews to study their reactions in face of danger and the fatigue factors involved, Capt. Bradley C. Brownson (formerly of Rochester) as flight surgeon of a medium bombardment squadron (in the central Pacific area) voluntarily participated in six combat strike sorties over heavily defended enemy held bases, during which time he was subjected to the dangers of enemy antiaircraft fire and probable fighter opposition." Dr. Brownson graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1937 and entered the service Aug. 15, 1941.

Captain Samuel Hurwitz

Capt. Samuel Hurwitz, formerly of Fall River, Mass., was recently awarded the Bronze Star Medal. The citation accompanying the award read "for heroic achievement in action on July 17, 1944 in France. When one of the battery positions of his battalion was subjected to heavy enemy shelling, Captain Hurwitz, battalion surgeon, immediately proceeded to the vicinity and began to render medical attention to the wounded. Despite the fact that more than twenty enemy shells landed in his battery's position during a period of forty-five minutes, Captain Hurwitz, completely disregarding his own safety, continually exposed himself to this enemy shell fire as he organized the first aid, rendered immediate medical attention to the wounded and caused their evacuation. The courage and devotion to duty displayed by Captain Hurwitz reflected credit on himself and the military service. Dr. Hurwitz graduated from the University of Toronto Faculty of Medicine in 1931 and entered the service Aug. 12, 1942.

Major John H. Grindlay

Major John H. Grindlay, former fellow in surgery at the Mayo Foundation and chief of professional medical services at McGuire General Hospital, Richmond, Va., has been awarded the Bronze Star Medal. The citation read, in part, "Major Grindlay with other United States military personnel and a number of civilians assisted in the destruction of military installations and equipment of benefit to the enemy and withdrew with General Stilwell from Burma to India. The trek was made on foot across mountains, jungle terrain and monsoon swollen streams. Major Grindlay's endurance, cheerfulness and concern for the welfare of other members of his party contributed much to the successful completion of this march." Dr. Grindlay graduated from Harvard Medical School, Boston, in 1935 and entered the service Nov. 25, 1940.

Captain Emanuel Sprei

The Bronze Star Medal was recently awarded to Capt. Emanuel Sprei, formerly of New York, accompanied by the citation "for meritorious service in connection with military operations against an enemy of the United States in France during the period July 29, 1944 to Oct. 31, 1944. He has repeatedly established his aid station immediately behind the front lines, thereby expediting the treatment and evacuation of the wounded. His professional knowledge and untiring efforts have enabled his medical detachment to function with precision and dispatch." Dr. Sprei graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1938 and entered the service Feb. 20, 1942.

NAVY

COMMISSIONING OF MEDICAL AND DENTAL STUDENTS

Commissioning of medical and dental students in the V-12 Program who are under 21 years of age at the time of their graduation from professional school is defined in a recent release (Navy V-12 Bulletin No. 273) issued by the Bureau of Naval Personnel, Washington, D. C., as follows:

As a result of the accelerated academic programs for medical and dental students in the Navy V-12 Program, it is anticipated that a limited number of such men will complete the requirements for graduation from medical or dental schools prior to their having attained the age of 21. As the laws of practically all the states require that applicants for license to practice medicine and dentistry be 21 years of age, it is considered highly desirable that such a requirement be maintained by the Medical Department of the Navy.

Therefore, in the event that a medical or dental student in the Navy V-12 Program completes his professional academic training before he attains the age of 21, he will be commissioned as Ensign H(P) (probationary) on graduation and will be assigned to active duty under the cognizance of the Bureau of Medicine and Surgery or, at his request, he may be released from active duty status until he has reached the age of 21. The services of such Ensigns H(P) assigned to active duty in the Navy will be utilized in laboratory work or in other duties not involving actual medical or dental treatment until they become 21 years of age, at which time they will be eligible for appointment as Lieutenants (jg), (MC), U. S. Naval Reserve, or Lieutenants (jg), (DC), U. S. Naval Reserve, and assignment to intern training or to general duty.

At the time recommendations for appointment to commissioned status on completion of requirements for graduation from medical or dental schools are forwarded in conformance with the requirements of reference (a), the commanding officer should recommend any man who will not have reached his twenty-first birthday for appointment as Ensign H(P) rather than Lieutenant (jg) (MC) or (DC) and, if the student wishes to exercise the privilege of requesting inactive duty, such written request will be forwarded by the commanding officer to this bureau via the Bureau of Medicine and Surgery.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Robert Moore Smith Jr.

Lieut. Robert Moore Smith Jr., formerly of Louisville, Ky., was recently awarded the Bronze Star. The citation read "for meritorious performance of duty as a company medical officer of the Second Beach Battalion during the assault of France, June 6, 1944. Lieutenant Smith, under heavy gunfire, repeatedly exposed himself to administer to the wounded and, without regard for his personal safety, supervised the evacuation of wounded from his section of the beach. His courage and devotion to duty were an inspiration to all officers and men having contact with him. The skill and professional ability displayed by Lieutenant Smith, under most trying conditions, were in keeping with the best traditions of the United States naval service." Dr. Smith graduated from Washington University School of Medicine, St. Louis, in 1940 and entered the service Feb. 8, 1943.

Lieutenant Commander Ralph Chandler Parker Jr.

Lieut. Comdr. Ralph Chandler Parker Jr., formerly of Batavia, N. Y., was recently awarded the Bronze Star. The citation reads "for meritorious service as Senior Medical Officer attached to the U. S. S. *Arkansas* prior to and during the invasion of the coast of France on June 6, 1944. Skilled and tireless in the performance of duty, Lieutenant Commander Parker achieved exceptional success in training the personnel of the Medical Department for the prompt and expert care and treatment of casualties brought aboard during assault operations.

His outstanding professional integrity and devoted efforts were responsible for the saving of many lives and in keeping with the highest traditions of the United States Naval Service." Dr. Parker graduated from Harvard Medical School, Boston, in 1937 and entered the service July 2, 1938.

Lieutenant Walter George Epply

Posthumous award of the Silver Star was recently made to Lieut. Walter George Epply, formerly of Manchester, N. H. The citation accompanying the award read "for conspicuous gallantry and intrepidity as officer in charge of the medical section of a beach party during the assault on enemy Japanese held Asan Point, Guam, Marianas Islands, on July 21, 1944. Landing with his medical section on a beach subjected to heavy and persistent enemy mortar and shellfire, Lieutenant Epply immediately located a suitable site and directed the establishment of his medical station. Completely disregarding his own personal safety and exposing himself continuously to terrific hostile fire, he skilfully rendered aid to the many casualties on the beach until he was killed while administering plasma to a wounded Marine, whose life was saved as a result of the prompt and vital treatment. Lieutenant Epply's heroic conduct and self-sacrificing efforts on behalf of his comrades were an inspiration to his corpsmen and in keeping with the highest traditions of the United States Naval Service. He gallantly gave his life for his country." Dr. Epply graduated from McGill University Faculty of Medicine, Montreal, in 1941 and entered the service Aug. 22, 1942.

Captain Bernard S. Pupek

The Legion of Merit was recently awarded to Capt. Bernard S. Pupek, formerly of Arlington, N. J. The citation read "For exceptionally meritorious conduct in the performance of outstanding services to the government of the United States as medical officer on the staff of Commander Amphibious Force, United States Atlantic Fleet, and later on the staff of a major task force commander during the landings in French Morocco. Charged with the difficult assignment of preparing thorough casualty evacuation plans in coordination with army medical authorities, Captain Pupek worked untiringly in providing loaded transports, shipborne landing craft and beach parties with adequate medical facilities and personnel to care for the wounded. By his sound judgment and outstanding initiative in organizing, training and directing the operations of the various assault unit medical departments, he contributed materially to the efficient and expeditious handling of casualties during the large scale amphibious attacks in this vital war area." Dr. Pupek graduated from New York University College of Medicine, New York, in 1925 and was commissioned a lieutenant (jg) in June of that year.

Captain Brython P. Davis

A letter of commendation was recently presented to Capt. Brython P. Davis, formerly of Washington, D. C., which reads "Your performance of duty over a period of thirty months as medical officer in command of a base hospital, Northern Ireland, has been brought to my attention. During your tour of duty the hospital and all of its facilities has been opened to the officers and men of all the Allied Forces as well as to our own. Not only were the ills of the patients treated skilfully, but you and your staff contributed materially to the creation of most cordial relations with the members of all Allied forces. For your leadership, tact, application of technical knowledge and skill, and steadfast devotion to duty you are hereby commended. This commendation carries with it the privilege of wearing the commendation ribbon." Dr. Davis graduated from the University of California Medical School, San Francisco, in 1916 and entered the service Aug. 29, 1917.

Lieutenant (jg) John L. Paladino

The Navy and Marine Corps Medal was recently bestowed on Lieut. (jg) John L. Paladino, formerly of Brooklyn. The citation read "for heroic conduct in caring for the survivors of the U. S. S. LST 314 subsequent to the sinking of that vessel."

on June 9, 1944. Although he himself was wounded and suffering from shock and prolonged exposure, Lieutenant, Junior Grade, Paladino promptly organized first aid parties aboard the rescue vessel and, working tirelessly and with expert professional skill for a period of eight hours, attended the survivors of his ship until he was satisfied that all possible medical aid had been rendered. His unselfish efforts and valiant devotion to duty under extremely difficult conditions were in keeping with the highest traditions of the United States Naval Service." Dr. Paladino graduated from St. Louis University School of Medicine in 1936 and entered the service in September 1943.

Lieutenant Roddie Lesley Stewart

Lieut. Roddie L. Stewart, formerly of Pell City, Ala., was recently awarded the Bronze Star for meritorious service as headquarters battalion surgeon during the attack on Saipan. The citation stated that he landed "during heavy artillery and mortar barrage and established and operated an aid station by means of which many casualties were cared for and evacuated." Dr. Stewart graduated from the University of Tennessee College of Medicine, Memphis, in 1934 and entered the service in August 1942.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Vaughan General Hospital, Hines, Ill.: Virus and Rickettsial Diseases: Medical and Neurologic Diseases and Treatment, Dr. Thomas Francis Jr., February 16; Psychosomatic Medicine, Drs. David Slight and Lewis J. Pollock, February 28.

Station Hospital, Dow Field, Bangor, Maine: Joint Injuries, Drs. G. E. Haggart and Hugh F. Hare, February 20.

Dispensary, U. S. Naval Air Station, Brunswick, Maine: Fractures of Extremities, Dr. Russell F. Sullivan, February 15. Station Hospital, Fort Williams, Portland, Maine: The Use of Penicillin and the Sulfa Drugs, Dr. Cutting B. Favour, February 15.

Regional Hospital, Waltham, Mass.: The Pneumonias and Other Respiratory Infections, Dr. Francis C. Lowell, February 15.

U. S. Naval Hospital, Chelsea, Mass.: The Psychoneuroses and Their Management, Dr. Abraham Myerson, February 15.

Lovell General Hospital, Fort Devens, Mass.: Pilonidal Sinus and Common Diseases of the Anus and Rectum, Dr. E. Parker Hayden, February 15.

Cushing General Hospital, Framingham, Mass.: Blood Dyscrasias and Transfusions, Dr. William B. Castle, February 15.

Station Hospital, Camp Myles Standish, Taunton, Mass.: Diarrheal Diseases, Dr. Ralph E. Wheeler, February 15.

U. S. Marine Hospital, Brighton, Mass.: The Skin, Dr. Bernard Appel, February 15.

U. S. Naval Convalescent Hospital, Springfield, Mass.: Burns and Reconstruction Surgery, Drs. John A. Reidy and John Langohr, February 15.

Dispensary, U. S. Naval Construction Training Center, Davisville, R. I.: Peripheral Vascular Disease, Dr. Robert R. Linton, February 15.

U. S. Naval Hospital, Newport, R. I.: Acute Abdominal Emergencies, Dr. Richard B. Cattell, February 15.

Station Hospital, Bradley Field, Windsor Locks, Conn.: The Skin, Dr. Maurice J. Strauss, February 15.

Naval Submarine Base, New London, Conn.: Chest and Abdominal Injuries, Drs. R. Glen Urquhart and George H. Gildersleeve, February 15.

Induction Center, Grand Central Palace, New York: Clinical Implications in the Newer Knowledge of the Shock Syndrome, Dr. Samuel Standard, February 23.

A. A. F. Langley Field, Virginia: Arteriovenous Fistula, Dr. William B. Porter, February 23; Common Peripheral Nerve Lesions and Technic of Repairing Large Nerve Defects, Capt. Benjamin B. Whitcomb, February 23.

Lieutenant Commander Ernest N. Neber

The Navy and Marine Corps Medal was recently awarded to Lieut. Comdr. Ernest N. Neber, formerly of Centralia, Ill. The citation read "for heroic conduct while serving as flight surgeon with a Marine fighter squadron on the occasion of an explosion at an advanced naval base in the Solomon Islands area on Sept. 4, 1943. When a large aerial bomb exploded and overturned a nearby truck, Lieutenant Commander (then Lieutenant) Neber unhesitatingly rushed to the aid of three men in the cab of the burning vehicle. Lifting him out of the compartment while ammunition from the gun pans of four blazing planes exploded around him, he carried an unconscious and badly burned victim to the safety of a revetment, where he skilfully administered emergency treatment. Seconds after he effected his daring and gallant rescue, a gasoline truck exploded and completely demolished the four planes and the overturned vehicle. Lieutenant Commander Neber's professional integrity and fearless devotion to duty, maintained at great personal risk, undoubtedly saved the life of a man who otherwise might have perished and were in keeping with the highest traditions of the United States Naval Service." Dr. Neber graduated from Hahnemann Medical College and Hospital of Philadelphia in 1936 and entered the service July 1, 1944.

Ashford General Hospital, White Sulphur Springs, W. Va.: Treatment of Patients with Paraplegia Due to War Injuries, Dr. Donald Munro, February 20.

Percy Jones General and Convalescent Hospital, Battle Creek, Mich.: Recent Advances in Virus and Rickettsial Diseases, Capt. Arthur W. Frisch, February 19; Surgical Diseases of the Stomach, Dr. Warren H. Cole, February 26.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, February 3, page 282)

ARKANSAS

Baptist State Hospital, Little Rock. Capacity, 340; admissions, 9,018. Mr. John G. Dudley, Administrator (intern, April 1).

CALIFORNIA

Mount Zion Hospital, San Francisco. Capacity, 193; admissions, 5,333. Dr. J. A. Katzive, Director (resident—roentgenology).

CONNECTICUT

Meriden Hospital, Meriden. Capacity, 177; admissions, 3,802. Dr. Herbert T. Wagner, Director (interns, July 1).

MASSACHUSETTS

St. Joseph's Hospital, Lowell. Capacity, 175; admissions, 4,358. Sister St. Philip, R.N., Administrator (interns). Worcester Hahnemann Hospital, Worcester. Capacity, 151; admissions, 4,457. Miss Erna M. Kuhn, R.N., Superintendent (2 interns, 2 residents).

MISSOURI

St. Mary's Hospital, Kansas City. Capacity, 182; admissions, 5,785. Sister Mary Liberata, R.N., Superintendent (1 intern now, 3 July 1).

NEW YORK

St. Francis Hospital, New York City. Capacity, 441; admissions, 6,788. Dr. John Dornning, Director (interns).

OHIO

Fairview Park Hospital, Cleveland. Capacity, 201; admissions, 6,170. Rev. Philip Vollmer Jr., Superintendent (2 interns, July 1). Lutheran Hospital, Cleveland. Capacity, 160; admissions, 4,525. Mr. Lee S. Lanpher, Superintendent (intern, July 1).

PENNSYLVANIA

Northeastern Hospital, Philadelphia. Capacity, 102; admissions, 2,455. Mr. Charles H. Dabb, Administrator (2 interns).

WISCONSIN

State of Wisconsin General Hospital, Madison. Capacity, 772; admissions, 12,682. Dr. H. M. Coon, Superintendent (resident—medicine; resident—ophthalmology-otology).

ORGANIZATION SECTION

THE PHYSICIAN'S FEDERAL INCOME TAX

PREPARED BY BUREAU OF LEGAL MEDICINE AND LEGISLATION, AMERICAN MEDICAL ASSOCIATION

On or before March 15, federal income taxpayers must do three things: (1) They must file their final returns for the year 1944; (2) they must file declarations of estimated tax for 1945; (3) they must pay the unpaid part, if any, of the tax that was unabated for 1942 or 1943, as the case may be.

WHO MUST FILE RETURNS

A tax return must be filed by every citizen or resident of the United States whose total gross income in 1944 was \$500 or more. Joint returns may be filed by a husband and wife if (1) they were married at the end of the year and (2) both were citizens or residents of the United States. Such a joint return may be filed even though one spouse had neither income nor deductions.

WHO MUST FILE DECLARATION OF ESTIMATES

In addition to filing the return for 1944, certain taxpayers must file on or before March 15 a declaration of estimated tax for 1945. Such a declaration must be filed by a taxpayer if—

(1) his gross income from wages can reasonably be expected to exceed the sum of \$5,000 plus \$500 with respect to each surtax exemption, except his own; or

(2) his gross income from sources other than wages can reasonably be expected to exceed \$100 for 1945 and his gross income to be \$500 or more.

A taxpayer may, if necessary, file one or more amended declarations during the year but only one in each calendar quarter. The last such amended declaration must be filed on or before Jan. 15, 1946.

The estimated tax is payable quarterly as it was in 1944, the final payment becoming due Jan. 15, 1946.

TAX RATES AND EXEMPTIONS

The victory tax has been eliminated and the normal rate reduced from 6 per cent to 3 per cent. The surtax rate begins at 20 per cent on the first \$2,000 of surtax net income and increases in rate for incomes in the higher brackets.

For the normal tax an exemption of \$500 is allowed each taxpayer, irrespective of the number of dependents or marital status. If a joint return is filed by husband and wife the exemption normally is \$1,000. If, however, the adjusted gross income of one spouse is less than \$500 the exemption claimable on the joint return is \$500 plus the amount of that adjusted gross income. For the surtax, exemptions are in the amount of \$500 each for the taxpayer, for his or her spouse and for each dependent whose gross income was under \$500. In prior years the personal exemption allowed a married couple could be taken in full on a joint return or on separate returns could be taken by either or divided between them in any desired proportion. This division can no longer be done.

The determination of whether a taxpayer is single or married is to be made as of the last day of the taxable

year. There is no status determination date for dependents, the test being whether the taxpayer furnished over half of the support. The requirement previously obtaining that the dependent must either be under 18 years of age or incapable of self support because of some mental or physical defect has been eliminated.

The earned income credit of 10 per cent, claimable in connection with the normal tax in prior years, has been eliminated. A special exemption is made available to taxpayers who are in the armed forces which will be discussed later.

GROSS AND ADJUSTED GROSS INCOMES

Gross Income.—A physician's gross income is the total amount of money received by him during the year for professional services, regardless of the time when the services were rendered for which the money was paid, assuming that the return is on a cash receipts and disbursements basis, plus such money as he has received from investments and from other sources.

If a physician receives a salary as compensation for services rendered and in addition thereto living quarters or meals, the value to the physician of the quarters and meals so furnished ordinarily constitutes income subject to tax. If, however, living quarters or meals are furnished for the convenience of the employer, the value thereof need not be computed and added to the compensation otherwise received by the physician. As a general rule, the test of "convenience of the employer" is satisfied if living quarters or meals are furnished to a physician who is required to accept such quarters and meals in order to perform properly his duties. For example, if a physician employed by a hospital is subject to immediate service at any time during the twenty-four hours of the day and therefore cannot obtain quarters or meals elsewhere without material interference with his duties and on that account is required by the hospital to accept the quarters or meals furnished by it, the value thereof need not be included in the gross income of the physician.

Adjusted Gross Income.—Adjusted gross income is defined to mean gross income minus—

(1) deductions attributable to a trade or business carried on by the taxpayer, if such trade or business does not consist of the performance of services by the taxpayer as an employee;

(2) expenses of travel, meals and lodging while away from home, paid or incurred by the taxpayer in connection with the performance by him of services as an employee;

(3) certain reimbursed expenses in connection with employment;

(4) deductions attributable to property held for the production of rents or royalties;

(5) depreciation or depletion allowed a life tenant of property or to an income beneficiary of property held in trust; and

(6) losses from the sale or exchange of property.

The adjusted gross income is to be used as a basis to determine (1) the limitation on the deduction for charitable contributions (15 per cent of the adjusted

gross income), (2) the amount of the deduction for medical expense (excess over 5 per cent of adjusted gross income), (3) the amount of the optional standard deduction the taxpayer may elect to take (10 per cent of adjusted gross income in certain income brackets), (4) exemptions in certain cases where joint returns are filed by husband and wife, as previously pointed out, and (5) if the taxpayer may take advantage of the optional tax table devised for incomes under \$5,000.

OPTIONAL TAX TABLE

If a taxpayer has an adjusted gross income of less than \$5,000, he may if he so elects compute his tax using the optional or alternative tax table. This table allows for the normal tax and surtax exemptions and for nonbusiness deductions approximating 10 per cent of the adjusted gross income. The election may be exercised irrespective of the source of the income. This table may not be used if the adjusted gross income of the taxpayer is \$5,000 or more but in such cases an optional flat \$500 deduction may be claimed in lieu of nonbusiness deductions generally, such as charitable contributions, interest and taxes. Such a taxpayer may elect to exercise this option or he may itemize such deductions as in prior years. The taxpayer who reports an adjusted gross income of less than \$5,000 a year will not be allowed the standard deduction as a separate item. Its benefits may be obtained only by using the optional tax table, which, as already indicated, assumes that the user of the table is entitled to a deduction approximating 10 per cent of his adjusted gross income.

PHYSICIANS IN SERVICE

The fact that a physician is in service does not of itself excuse a failure to file a return or declaration. It is understood, however, that if because of the inaccessibility of the necessary records a physician in service is unable to file a complete return he may file a tentative return on which he must estimate his income, deductions and tax as best he can and indicate on the return his reasons for following the procedure. At a later date, if that procedure is followed, a complete return must be filed and necessary adjustments in tax will be made. What has just been said relates to physicians in service who are stationed in this country.

If a physician in service is on duty outside the United States, no income tax will become due, generally speaking, until the fifteenth day of the fourth month following the month in which the physician ceases, except by reason of death or incompetence, to be a member of the military forces on sea duty or in service outside the continental United States, or the fifteenth day of the third month following the month in which the present war is terminated, whichever may be the earlier. When a physician in service returns to the United States, he should contact his local collector of internal revenue and make arrangements to bring his returns up to date.

The law provides a special exemption for members of the armed forces in addition to the personal exemption. The first \$1,500 of the service pay of members of the armed forces, including commissioned officers, is non-taxable. Other service pay, however, must be reported as income. Commutation of quarters and rental value of quarters occupied by medical officers are not taxable income; neither is mustering out pay.

If the ability of physicians in service to pay income taxes is materially affected by such service, payment

of the tax falling due before or during the service may be deferred for a period extending not more than six months after the termination of service. This deferment is authorized by section 513 of the Soldiers' and Sailors' Civil Relief Act of 1940 and applies to all members of the Army, Navy, Marine Corps and Coast Guard and to all officers of the United States Public Health Service detailed for duty either with the Army or with the Navy, on active duty or while undergoing training or education under the supervision of the United States preliminary to induction into service. This deferment is not automatic. The taxpayer must present evidence to show that his ability to pay is materially impaired by reason of military service. Proof of that impairment should be submitted at the time the tax is due, on a form procurable at the offices of the several collectors of internal revenue.

Any tax owed by a member of the military or naval forces who dies in service will be canceled, this relief being retroactive to Dec. 7, 1941. If the tax has already been assessed at the time of the death of the person in service it will be abated. If the tax has already been collected it will be refunded as overpayment. This tax forgiveness applies only to income taxes and not to the estate tax.

The cost of equipment of an army officer or navy officer is deductible only to the extent that it is especially required for his profession and does not merely take the place of articles required in civilian life. The cost of uniforms is considered a personal expense and hence not deductible. The cost of gold braid and cap devices required by regulations of the Navy to be worn on the clothing of a naval officer has been held to constitute an expense necessitated by reason of his profession as an officer and to be deductible as a business expense.

DEDUCTIONS FOR PROFESSIONAL EXPENSES

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless he is prepared to prove the expenditure by competent evidence. So far as practicable, accurate itemized records should be kept of expenses and substantiating evidence should be carefully preserved. The following statement shows what such deductible expenses are and how they are to be computed:

Office Rent.—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment for use as a residence as well as for office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in such dwelling house or apartment, he may not, however, deduct any part of the rent of such house or apartment as professional expense; to entitle him to such a deduction he must have an office there, with regular office hours. If a physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

Office Maintenance.—Expenditures for office maintenance, as for heating, lighting, telephone service and the services of attendants, are deductible.

Supplies.—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using; for instance, dressings, clinical thermometers, drugs and chemicals. Pro-

professional journals may be classified as supplies and the subscription price deducted. Amounts currently expended for books, furniture and professional instruments and equipment, "the useful life of which is short," generally less than one year, may be deducted, but if such articles have a more or less permanent value, their purchase price is a capital expenditure and is not deductible.

Equipment.—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment such as has been described, for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical and laboratory equipment of more or less permanent nature, and instruments and appliances constituting a part of the physician's professional outfit, to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment and the purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired, nevertheless it may be recovered through depreciation deductions taken year by year over its useful life, as described later.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductible each year as depreciation. The amount depends to some extent on the nature of the property and on the extent and character of its use. The length of its useful life should be the primary consideration. The most that can be done is to suggest certain average or normal rates of depreciation for each of several classes of articles and to leave to the taxpayer the modification of the suggested rates as the circumstances of his particular case may dictate. As fair, normal or average rates of depreciation, the following have been suggested: automobiles, 25 per cent a year; ordinary medical libraries, x-ray equipment, physical therapy equipment, electrical sterilizers, surgical instruments and diagnostic apparatus, 10 per cent a year; office furniture, 5 per cent a year.

The principle governing the determination of all rates of depreciation is that the total amount claimed by the taxpayer as depreciation during the life of the article, plus the salvage value of the article at the end of its useful life, shall not be greater than its purchase price. The physician must in good faith use his best judgment and claim only such allowance for depreciation as the facts justify. The estimate of useful life, on which the rate of depreciation is based, should be carefully considered in each individual case.

Medical Dues.—Dues paid to societies of a strictly professional character are deductible. Dues paid to social organizations, even though their membership is limited to physicians, are personal expenses and not deductible.

Postgraduate Study.—The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible.

Traveling Expenses.—Traveling expenses, including amounts paid for transportation, meals and lodging, necessarily incurred in professional visits to patients

and in attending medical meetings for a professional purpose, are deductible.

Automobiles.—Payment for an automobile is a payment for permanent equipment and is not deductible. The cost of operation and repair, and loss through depreciation, are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance, repairs, garage rental (when the garage is not owned by the physician), chauffeur's wages, and the like.

Deductible loss through depreciation of an automobile is the actual diminution in value resulting from obsolescence and use and from accidental injury against which the physician is not insured. If depreciation is computed on the basis of the average loss during a series of years, the series must extend over the entire estimated life of the car, not merely over the period in which the car is possessed by the present taxpayer.

If an automobile is used for professional and also for personal purposes—as when used by the physician partly for recreation, or so used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted. A physician doing an exclusive office practice and using his car merely to go to and from his office cannot deduct depreciation or operating expenses; he is regarded as using his car for his personal convenience and not as a means of gaining a livelihood. What has been said in respect to automobiles applies with equal force to horses and vehicles and the equipment incident to their use.

MISCELLANEOUS

Contributions to Charitable Organizations.—For detailed information with respect to the deductibility of charitable contributions generally, physicians should consult the official return blank or obtain information from the collectors of internal revenue or from other reliable sources. Attention is called to the change in the law that applies to deductions for charitable contributions, namely, that an individual taxpayer can deduct such contributions only to the extent that they do not exceed 15 per cent of his adjusted gross income. The physician may not deduct as a charitable contribution the value of services rendered an organization operated for charitable purposes.

Bad Debts.—Physicians who make their returns on a cash receipts and disbursements basis, as most physicians do, cannot claim deductions for bad debts.

Taxes.—Taxes generally, either federal or state, are deductible by the person on whom they are imposed by law. Both real and personal property taxes are deductible; but so-called taxes, more properly assessments, paid for local benefits, such as street, sidewalk and other like improvements, imposed because of and measured by some benefit inuring directly to the property against which the assessment is levied, do not constitute an allowable deduction from gross income. Physicians may deduct state gasoline taxes and state sales taxes. In some states sales taxes are imposed on the seller, but, if they are passed on to the buyer, the latter may deduct them.

State income and use taxes are deductible; federal income taxes are not. Federal import, excise or stamp taxes are deductible only to the extent that they are attributable to business activities. This represents a change in the law applicable to 1944 and subsequent taxes. State automobile license fees are deductible. If a state or local fee is imposed for regulatory purposes,

and not to raise revenue, the fee may not ordinarily be deducted as a tax. If such fees, however, are classifiable as a business expense, they are deductible as such. Annual registration fees imposed on physicians probably come within the category of regulatory fees and should be deducted as a business expense rather than as taxes. Local and state occupational taxes imposed on physicians are deductible either as taxes or as a business expense, depending on the purpose for which the tax is imposed.

The excise taxes imposed on employers by section 804, title VIII, and section 901, title IX, of the Social Security Act, commonly referred to as old age and unemployment benefit taxes, are deductible annually by employers in computing net income for federal income tax purposes. If the taxpayer's return is made on a cash basis, as are the returns of practically all physicians, the taxes are deductible for the year in which they are actually paid. If the return is made on an accrual basis, the taxes are deductible for the year in which they accrue, irrespective of when they are actually paid. Employees, including physicians whose employment brings them within that category, may not deduct the tax imposed on them by section 801, title VIII, of the Social Security Act, generally referred to as the old age benefits tax. If, however, the employer assumes payment of the employee's tax and does not withhold the amount of the tax from the employee's wages, the amount of the tax so assumed may be deducted by the employer, not as a tax paid but as an ordinary business expense.

Medical Expense.—A taxpayer may deduct amounts expended for medical, dental and hospital care for himself, his spouse or a dependent, not compensated for by insurance or otherwise, including amounts paid for accident and health insurance, according to a prescribed formula. Deductions will be permitted to the extent that such expenses exceed 5 per cent of the adjusted gross income of the taxpayer but not in excess of \$2,500 in case of a taxpayer with more than one surtax exemption, or \$1,250 in case of a taxpayer with only one surtax exemption.

Laboratory Expenses.—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

Losses by Fire or Other Causes.—Loss of and damage to a physician's equipment by fire, theft or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

Insurance Premiums.—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise.

Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

Expense in Defending Malpractice Suits.—Expense incurred in the defense of a suit for malpractice is deductible as a business expense.

Sale of Spectacles.—Oculists who furnish spectacles, etc., may charge as income money received from such sales and deduct as an expense the cost of the article sold. Entries on the physician's account books should in such cases show charges for services separate and apart from charges for spectacles, etc.

Official Notes

DOCTORS LOOK AHEAD

The American Medical Association and the National Broadcasting Company are presenting the twelfth consecutive season of nationwide network health broadcasts weekly from January 6 to June 30, 1945. Included in the series are broadcasts relating to wartime and postwar developments, with special emphasis on medical progress of the present day and what it foreshadows for the nation's health in the immediate future.

Topics in the series, which is called *Doctors Look Ahead*, will be announced weekly in *THE JOURNAL* and monthly in *Hygeia*. Fast moving events may, however, cause last minute substitutions. Local newspapers should be consulted for announcements of time and stations. The program will be broadcast each Saturday at 4 p. m. Eastern War Time (3 p. m. Central, 2 p. m. Mountain and 1 p. m. Pacific War Time). When conflicts exist with local programs, rebroadcast may be arranged at hours other than on the network schedule. The next three topics are:

- February 10. Heart Surgery (Dr. Edwin P. Jordan).
- February 17. Refrigeration Anesthesia.
- February 24. Discharged Soldier.

The broadcast will be under the supervision of the Bureau of Health Education, whose director, Dr. W. W. Bauer, will summarize each program except when another speaker is announced.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Change in Status.—H. R. 1752 has passed the House, proposing a mobilization of civilian manpower. When this bill was being discussed on the floor of the House, Representative Edwin Arthur Hall, New York, submitted an amendment proposing that registered male nurses performing duties comparable to the duties performed by members of the Army Nurse Corps female or the Navy Nurse Corps female, when inducted into the armed forces, shall be inducted only as commissioned officers. A point of order against the amendment was sustained.

Bills Introduced.—S. Res. 62, submitted by Senator Pepper, Florida, proposes a continuation during the Seventy-Ninth Congress of the studies and surveys made by the Pepper Subcommittee on Wartime Health and Education and an additional \$25,000 to cover the expenses of the subcommittee. H. R. 1812, introduced by Representative Andrews, New York, proposes to authorize an award of merit for uncompensated personnel of the Selective Service System, including local board examining physicians and dentists and members of medical advisory boards. H. R. 1820, introduced by Representative Coffee, Washington, proposes a federal appropriation of \$18,000,000 for the fiscal year ending June 30, 1945 to enable the states to provide medical care for recipients of public assistance. Thereafter, the bill provides, a sum will be appropriated for each fiscal year sufficient to carry out the purposes of the bill. H. R. 1832,

introduced, by request, by Representative Kilburn, New York, proposes to provide pension, compensation or retirement pay of not exceeding \$20 per month to all veterans without dependents while being furnished hospitalization by the United States or any political subdivision.

THE HILL-BURTON BILL

In the discussion of the Hill-Burton bill which was published in *THE JOURNAL*, January 27, page 231, regarding allotments of funds to the states for surveys and development of programs, it was emphasized that the bill did not contain any specific provision for advice from the Federal Advisory Council as far as these allotments are concerned. The bill does provide, however, that allotments for construction and administrative expenses are to be made under regulations promulgated by the Surgeon General of the United States Public Health Service on "recommendation of the Federal Advisory Council, and after consultation with the agencies designated in accordance with section 622 (a) (2)" of the bill.

STATE LEGISLATION

Arkansas

Bill Introduced.—S. 58 proposes that an action against a physician, dentist or hospital for malpractice, error, mistake or failure to treat or cure must be commenced within two years after the cause of action accrues.

California

Bills Introduced.—S. 160 proposes to enact a separate naturopathic practice act and to create an independent board of naturopathic examiners to examine and license applicants for licenses to practice naturopathy, defined in the bill as "the treatment of the sick and afflicted by the use of such substances as light, air, water, clay, heat, rest, diet, herbs, electricity, massage, Swedish movements, suggestive therapeutics, magnetism, physical and mental culture." S. 183 proposes to permit the formation of local hospital districts and to authorize the establishment, organization and operation of public hospitals in such districts. S. 219 proposes to authorize associations duly licensed by the state department of public welfare to enter into contracts with subscribers to pay for medical and hospital services to be rendered by hospitals and by licensed physicians. Such an association may consist of physicians or lay corporations formed for such purposes. A. 111 proposes that osteopathic practitioners be embraced within the term "physician" as used in the law conditioning the issuance of a license to marry on the presentation by each party to the proposed marriage of a physician's certificate that the party is free from stated venereal diseases. A. 112 proposes that chiropractors be embraced within the term "physician" within the meaning of the law that limits the retail sale of venereal prophylactics to sale on the prescription of a licensed physician. A. 128 and A. 420 propose to prohibit the state department of social welfare from adopting or enforcing any rule or regulation the operation of which results in discrimination against practitioners of any branch of the healing arts. A. 236, to supplement the medical practice act, proposes to permit certain chiropractors to be issued physician's and surgeon's certificates after successfully passing examinations in biochemistry, advanced bacteriology and pathology, surgery, materia medica, pharmacology and therapeutics, general medicine, and advanced obstetrics and gynecology. Such chiropractors, after being issued physician's and surgeon's certificates, are to respond only to the board of chiropractic examiners in such proceedings to revoke or suspend their licenses as may be instituted in the future. A. 449, A. 800 and A. 1200 propose to establish varying systems of compulsory health insurance. A. 637 proposes to add to the Health and Safety Code a division 22 entitled "Hypnotic Drugs," which proposes to prohibit the sale or distribution of any hypnotic drug except on the written prescription of a licensed physician, dentist, chiropodist or veterinarian. Hypnotic drug is defined to mean "veronal, barbital (acid diethylbarbituric) or other barbituric acid derivative, demerol, mescaline, acetylurea, paraldehyde, chloral hydrate, hydantoin, sulfonated methanes, or their salts, derivatives or compounds of the foregoing substances, or any preparation containing any of the foregoing substances, or their

salts, derivatives or compounds, amphetamine, its salts or other compounds, or any preparation containing any amphetamine." A. 653, to amend the laws restricting the distribution and possession of narcotic drugs, proposes so to define narcotic drugs as to include "veronal, barbital (acid diethylbarbituric) or other barbituric acid derivative, demarol, mescoline, acetylurea, paraldehyde, hydantoin, sulfonated methanes, or their salts, derivatives or compounds of the foregoing substances, or any preparation containing any of the foregoing substances, or their salts, derivatives or compounds, amphetamine, its salts or other compounds, or any preparation containing any amphetamine excepting inhalers denatured to be unfit for internal use."

Connecticut

Bills Introduced.—S. 32 proposes to authorize the establishment and operation of a state hospital for inebriates. S. 84 proposes so to amend the charter of the Connecticut State Medical Society as to make the members of the council of the society members of its house of delegates. S. 129 proposes to prohibit the use of the roentgen ray, the x-ray or radium for the therapeutic or cosmetic treatment of another person except either by or under the prescription, direction or supervision of a licensed physician, osteopath or dentist. H. 188 proposes to require the department of health to cause to be printed and mailed by June 1 annually a list of all registered practitioners of medicine, midwifery, chiropractic, osteopathy, naturopathy, chiropody, nursing or physiotherapy. The present law requires such a list to be printed and distributed prior to March 1. H. 193, to amend the narcotic drug act, proposes so to define the term "narcotic drugs" as to include isonipecaine, which is defined as "the substance identified chemically as 1-methyl-4-phenyl-piperidine-4-carboxylic acid ethyl ester, or any salt thereof by whatever trade name identified."

Georgia

Bill Introduced.—H. 94 proposes to enact a new vital statistics law providing for the compulsory registration of births, stillbirths and deaths and to require the registration of foundlings.

Illinois

Bills Introduced.—H. 23 proposes to authorize the furnishing at public expense of chiropractic and osteopathic treatment to persons receiving old age pension grants from the state. H. 24 proposes to appropriate \$342,000 to the Medical Center Commission created by the act approved June 4, 1941 in relation to the establishment of a medical center district in Chicago.

Indiana

Bills Introduced.—H. 73 proposes to create in cities of the first class having a population of more than 300,000 a department of public health and hospitals and a public health and hospitals district, apparently designed to operate public hospitals in the area involved. H. 143, to supplement the medical practice act, proposes to abolish the state board of medical registration and examination and to transfer its powers, duties and functions to a board of medical registration and examination of Indiana, which the bill proposes to create. The new board is to consist of five nonsectarian physicians, one osteopath and one chiropractor. H. 180 proposes so to amend the narcotic drug act as to include within the regulations imposed thereby isonipecaine.

Iowa

Bills Introduced.—S. 55 and H. 80, to amend the laws relating to the issuance of licenses to practitioners of the healing art and allied vocations, proposes to make it a ground for the revocation of such licenses for the holders thereof to quote a guaranty, price, terms or other special inducement prior to consultation. The bill proposes, however, that the provisions just referred to shall not apply to barbers, cosmetologists, pharmacists or embalmers. S. 128, to amend the law authorizing the establishment of corporations to operate nonprofit hospital service plans, proposes also to authorize such corporations to contract to furnish medical and surgical services to subscribers and to contract for the furnishing of such services with physicians and osteopaths.

Kansas

Bill Introduced.—S. 23 proposes to repeal the laws regulating the manufacture, sale, prescribing or possession of narcotic drugs and to enact what appears to be the uniform narcotic drug act.

Maine

Bills Introduced.—S. 65 proposes to expand the definition of the practice of chiropractic to include treatment by hydrotherapy or diet. S. 66 proposes to authorize any member of the Maine state chiropractors' association or any licensed chiropractor to use the title "Doctor" or the letters "Dr." to his name when accompanied by the word "Chiropractor." S. 67 proposes to require applicants for licenses to practice chiropractic to be examined, in addition to the subjects now enumerated in the law, in electrotherapy, hydrotherapy and dietetics. H. 155 proposes to require applicants for licenses to practice chiropractic to have completed a course in chiropractic schools of four school years of not less than nine months each and of a total of 3,600 school hours. The present law requires completion of a course of four school years of not less than six months each and of a total of 2,600 sixty minute school hours. H. 156 proposes that the certificate issued a successful applicant for a license to practice chiropractic shall designate the holder as a doctor of chiropractic, chiropractor or chiropractic physician. The present law specifically only requires the license to designate the holder as a doctor of chiropractic. H. 147, to amend the workmen's compensation act, proposes to authorize a chiropractor to furnish the medical care that an employer is required to furnish an injured workman.

Maryland

Bill Introduced.—H. 149 creates in the state board of health a Bureau of Medical Services which is to administer a program of medical care in the state for indigent and medically indigent persons. The bureau is authorized to contract with physicians, dentists and hospitals for the necessary medical, surgical and hospital treatment of eligible persons.

Missouri

Bill Introduced.—H. 79 authorizes the state commissioner of health to distribute to local health officers and health boards antitoxin and other biologic products and to process and distribute to such agencies blood plasma.

Montana

Bill Introduced.—H. 42 proposes to authorize the state health department to obtain, process and distribute blood plasma.

Nebraska

Bills Introduced.—Bill 112 proposes to require every licensed chiropractor in the state to attend not less than three days annually such "scientific" clinics, forums or chiropractic educational study as may be approved by the state examining board in chiropractic as a prerequisite for the annual renewal of his or her license. Bill 113 proposes to amend the definition of an accredited school of chiropractic within the meaning of the chiropractic practice act. Such a school, among other things, the bill proposes, must conduct a clinic for patients in which students regularly participate; it must give instruction in anatomy, orthopedics, physiology, embryology, chemistry, pathology, hygiene and sanitation, bacteriology, symptomatology, histology, spinal analysis, diagnosis, principles and practices of chiropractic, including palpation, nerve tracing and adjusting, and especially require clinical instruction in the last three named subjects of no less than four hours per week during the last two terms of instruction; and it must require an actual attendance of four college years totaling not less than four thousand hours.

Nevada

Bill Introduced.—A. 20 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a certificate of a licensed physician, based on examination and a standard serologic test made not more than thirty days prior to the date of the application, that the party either is not infected with syphilis or if so infected is not in a stage of that disease that is or may become communicable to the marital partner.

New Hampshire

Bill Introduced.—H. 77 proposes apparently to condition employment in a restaurant on the possession of a physician's certificate that the holder thereof is not afflicted with tuberculosis, venereal disease in a communicable state or with any other communicable disease.

New Mexico

Bill Introduced.—H. 21 proposes to exempt from the provisions of the emergency school tax act fees and charges made by hospitals, physicians, osteopaths, chiropractors or dentists for care rendered the sick or disabled.

New York

Bills Introduced.—S. 212 proposes that if a patient in any public hospital needs blood transfusions it shall be the duty of the responsible hospital administrator without delay to provide such transfusions, if obtainable. If the patient is unable to pay therefor, the bill proposes that the state reimburse the hospital for the cost thereof. S. 217, to amend the workmen's compensation act, proposes to authorize an injured employee when dental care is required to select any dentist authorized to do so to treat him. S. 258 and A. 610 propose to make a hospital bill, certified to by a hospital superintendent admissible in evidence and prima facie evidence of the facts therein contained, subject, however, to rebuttal. A. 342 proposes to require every physician to report to designated health authorities every case of infantile paralysis under his care. S. 515 and A. 434 propose that, on the refusal of any person suspected of being infected with venereal disease to submit to the required examination or to permit specimens of blood or bodily discharges to be taken for laboratory examination or to comply with the restrictions imposed by quarantine, the appropriate officer may apply to the court for an order compelling compliance, and the court is to be empowered to enter such an order. The bill further proposes to make the duty of appropriate boards of health to provide adequate facilities for the free diagnosis and treatment of persons living within its jurisdiction infected or suspected of being infected with venereal disease. S. 372 and A. 445 propose that the provisions of the law prohibiting the handling of live pathogenic micro-organisms or viruses, other than vaccine virus, except by licentiates of the state commissioner of health or the city commissioner of health of New York City, shall not apply to diseased tissue, exudate or other specimens which are sent by physicians to laboratories for examination as an aid in the diagnosis or control of disease. S. 445 and A. 548 propose so to amend the unemployment compensation act as to include within its provisions persons employed in the preparation and/or handling of food for human consumption in hospitals, educational institutions and religious institutions. S. 476 proposes to establish a system of compulsory health insurance. A. 372, to amend the law according liens to hospitals on claims or recoveries of patients, proposes that the lien shall be exclusive of personal services rendered by a physician.

North Dakota

Bills Introduced.—S. 57 and S. 58 proposes so to amend the narcotic drug act as to include within the regulation imposed thereby isonipecaine. S. 64 proposes to prohibit any person from engaging in the business of a nonprofessional nurse or from acting as a nonprofessional nursing attendant, auxiliary worker, subsidiary worker or vocational nurse or from caring for the sick for hire without first being licensed by the state board of nurse examiners. To be qualified for a license an applicant must be 20 years or older, be of good moral character, be in good physical and mental health, possess at least an eighth grade education, have successfully completed an accredited course for the training of practical nurses and be a citizen of the United States.

Oregon

Bill Introduced.—H. 53 proposes to require boards of directors of school districts to provide programs of health instruction and physical education for elementary and high school pupils.

Oklahoma

Bill Introduced.—H. 164 proposes to authorize the state commissioner of health to quarantine, isolate and confine any person whom he finds to be infected with any kind of venereal disease.

Pennsylvania

Bills Introduced.—H. 54 proposes to authorize the various professional licensing boards of the commonwealth to revoke or suspend the license of any physician, osteopath, veterinarian, pharmacist or registered nurse who has pleaded guilty, entered a plea of nolo contendere or who has been found guilty of violating any state or federal law pertaining to the sale, use or distribution of narcotics. S. 90 proposes to appropriate \$100,000 to the department of health for cancer research. S. 162 proposes to require every practicing physician to notify designated health officials of every case of tuberculosis coming under his observation. If an infected person is unable or unwilling so to conduct himself as not to expose his family or the public, appropriate courts are to be authorized to order his commitment to any approved institution established for the care of tuberculosis. H. 111 proposes to require every physician diagnosing a case of venereal disease to report the facts to the state department of health. Any infected person refusing to submit to treatment may, on application to the state department of health, be committed to an appropriate institution for treatment until the disease has been rendered noninfectious. H. 117, to amend the law conditioning the issuance to marry on the presentation by each party to the proposed marriage of a certificate of a physician licensed in Pennsylvania that the party is free from stated venereal diseases, proposes also to recognize such a certificate executed by a medical officer of the United States Public Health Service, Army or Navy. H. 191, to amend the narcotic drug act, proposes so to define the term "narcotic drug" as to include "any substance identified chemically as 1-methyl-4-phenylpiperidine-4-carboxylic acid ethyl ester or any salt or derivative thereof by whatever trade name designated or any preparation containing such substance or its salts or derivatives." H. 196, to amend the medical practice act, proposes to authorize the board of medical education and licensure to issue a temporary license to practice to a graduate of an approved medical school who has been licensed to practice in another state and who has served in the active military, naval or public health service in the present war as a commissioned medical officer. H. 246 proposes to authorize the board of medical education and licensure to license, after examination, persons to practice chiropody, defined in the bill as "the diagnosis and treatment of ailments of the human foot." Such a license does not confer the right to amputate the leg, foot or toes or to use any anesthetic other than local or to treat any constitutional disease.

South Carolina

Bills Introduced.—H. 23 proposes to authorize cities of over 70,000 to impose an occupational tax, not exceeding 20 per cent of gross income, on a person practicing any calling, business or profession within the limits of the city. Exempted, however, are teachers and ministers of the gospel. S. 49 proposes to authorize the establishment of nonprofit corporations to operate hospital service plans whereby such corporations undertake to pay for hospital care rendered by hospitals to subscribers to such plans.

South Dakota

Bills Introduced.—S. 48 and S. 107 proposes so to amend the definition of narcotic drugs within the meaning of the narcotic drug act as to include isonipocaine, which is defined as "the substance identified chemically as 1-methyl-4-phenylpiperidine-4-carboxylic acid ethyl ester or any salt thereof, by whatever trade name identified." S. 62 proposes to prohibit the operation of any hospital, maternity home, sanatorium, rest home, nursing home, boarding home or other related institution without the possession of a license from the state board of health." S. 108 proposes to authorize the establishment of nonprofit corporations to operate hospital service plans whereby such corporations undertake to pay for hospital care rendered by hospitals to subscribers to such plans.

Washington Letter

(From a Special Correspondent)

Feb. 5, 1945.

Draft of Nurses Urged by Representative Mary T. Norton

Legislation to draft nurses for the armed forces will be supported by Representative Mary T. Norton, Democrat of New Jersey, who is chairman of the House Labor Committee. She said that the voluntary system has failed and that the need for registered nurses is too urgent to delay further in the hope that enough nurses will eventually be recruited. Hearings on the draft legislation were resumed today before the House Military Affairs Committee. Explaining her stand, Representative Norton said "The Army says it requires a draft law to assure adequate care for our wounded. That's enough for me. I've supported everything the Army and Navy have considered essential to winning this war and I'll go along with this."

Another veteran woman congresswoman, Representative Edith Nourse Rogers, Republican of Massachusetts, has introduced a bill to draft nurses under Selective Service. Her bill involves national registration of all graduate nurses between 20 and 45 and authorizes the induction of all those who are eligible if required. Drafted nurses would be commissioned as second lieutenants in the Army and ensigns in the Navy.

Representative Frances P. Bolton, Republican of Ohio, says she will support legislation to induct nurses. The Rogers bill and another seeking the same objective, introduced by Representative Andrew J. May, Democrat of Kentucky, are before the Military Affairs Committee.

Veterans Branch Raps Veterans Hospitals

A Washington branch of a veterans organization has had its criticism of Veterans Administration handling of veterans hospitals placed in the *Congressional Record*. It charges that "bureaucratic obstructionism, red tape and simple inertia" emanate from the office of veterans affairs. A spokesman said "Under the policies of General Hines many thousands of sick and disabled veterans have been deprived of urgent hospitalization and medical care. His figures show that his administration has seen fit to add only 8,404 beds to its existing facilities throughout the United States since Pearl Harbor. Nothing should be left undone to provide reasonable care for our veterans to help in their rehabilitation physically, educationally, industrially and in any other way."

Nurses Commissioned in January

A total of 1,050 nurses was commissioned in the Army Nurse Corps during January, reports Surg. Gen. Norman T. Kirk. This represents a gain of 443 appointments over December. "The total is far short of the need for additional registered nurses," General Kirk said. An average of 250 nurses leave the service monthly, largely because of physical disability, which makes a net gain for January of around 800.

Medical Wacs Enlisted to Help Nurses

To relieve the shortage of nurses in service hospitals, an enlistment program for medical Wacs has been announced. For the first time since the Women's Army Corps was created, women may now enlist for service at a particular hospital. Girls must be willing to be transferred if the need arises, and they can enlist for service in any state. General Marshall has announced that the corps needs 8,000 additional members at once.

More Medical Officers and Nurses to Be Commissioned

Interviews started today for additional medical officers and nurses to be commissioned in the Regular Corps of the Public Health Service, Surg. Gen. Thomas Parran announces. Written examinations are scheduled for April 23, 24 and 25. Medical officers will be appointed in the grades of assistant surgeon and senior assistant surgeon. Nurses will be appointed in the grades of junior assistant nurse officer, assistant nurse officer and senior assistant nurse officer.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Board Continues Case of Dr. Housman.—At a recent meeting of the state board of medical examiners the board continued until March action on the application of Nathan S. Housman, formerly of San Francisco, for restoration of his license to practice medicine. The license had been revoked after he was convicted of keeping improper narcotic records and of perjury in his testimony at the trial (*THE JOURNAL*, Dec. 13, 1941, Jan. 24, 1942 and Feb. 13, 1943, p. 530).

Dr. Hanley Resigns as Maternal and Hygiene Director.—Dr. Bernard J. Hanley, member of the Los Angeles Health Department since 1926, has resigned as director of the bureau of maternal and child hygiene of the Los Angeles City Department of Health, effective December 31, according to the *Los Angeles Times*. He has been succeeded by Dr. Samuel M. Martins, clinic supervising physician. Dr. Hanley will continue to assist the department without compensation when needed.

Personal.—Dr. Karl Ludwig Schaupp, associate clinical professor of obstetrics and gynecology, Stanford University School of Medicine, San Francisco, was recently appointed a member of the board of education of San Francisco.—Dr. Wei Chang Chu, instructor in pharmacology, Kweiyang Medical College, arrived in San Francisco January 24 on leave for two years from the Chungking government for work in the department of pharmacology, Stanford University School of Medicine, San Francisco. Dr. Chu graduated at the Hunan-Yale Medical College in 1937.

Local Celebration of Discovery of Anesthesia.—The planting of a redwood tree and the dedication of a memorial tablet in Golden Gate Park formed a part of the celebration in San Francisco recently of the one hundredth anniversary of the discovery of anesthesia. The principal speaker at the park celebration was Chauncey D. Leake, Ph.D., dean and vice president of the University of Texas Medical Branch, Galveston, whose subject was "Horace Wells and His Contribution to Humanity." Other speakers on the program included Drs. Hubert R. Hathaway and William B. Neff, San Francisco, on "The Development of the Knowledge of Anesthetics." Dr. Leake gave a second address entitled "No More Pain." The observance was under the sponsorship of the state and local dental groups.

CONNECTICUT

Proposed Merger of New Haven and Grace Hospitals.—The proposed merger of New Haven and Grace hospitals, New Haven, was approved January 26 by the board of directors of both hospitals. Final ratification of the program rests with the Grace Hospital Society and the General Hospital Society of Connecticut, the parent associations of the units involved, newspapers reported. If the consolidation is carried out a public subscription drive for from three to four million dollars to erect and equip a new building will be a feature of the development. The proposed building, which would be erected near New Haven Hospital, would give the combined institutions a bed capacity of 850. It would be associated with the Yale University School of Medicine, it is planned, and a board of directors representing a merger of the boards of both hospitals would be entrusted with the overall supervision. The assets and liabilities of the hospitals would be pooled and endowment funds of each institution carried into a new project without sacrifice of identity or loss of the original intent of the donors. Two medical boards, operating in different spheres, will control the medical practices of the hospitals. One, representing the present staff committee of Grace Hospital and the private pavilion staff at New Haven Hospital, would govern medical practice in the new unit, which would include the new building plus a number of private and semiprivate beds in the present plant of New Haven Hospital. The other, to be appointed by the board of directors on nomination of Yale University through the school of medicine, would govern medical practice in some 350 ward beds and certain private and semiprivate beds assigned to it. All of these are now located in New Haven Hospital. Yale would

continue to contribute to the operating costs of these ward beds. These medical boards will be given the responsibility of developing medical standards and of training interns and resident staffs for their respective units. Residents and interns of both would be eligible to serve at the New Haven Dispensary. In a statement to the press endorsing the project Dr. Creighton Barker, New Haven, executive secretary of the Connecticut State Medical Society, called the development a "great forward step, in meeting the increasing demands for hospitalization and fine medical care in New Haven and surrounding territory."

ILLINOIS

Death from Toxoplasmosis.—The Illinois State Department of Public Health announced on January 27 that the first known death from toxoplasmosis in Illinois had been reported, stating that, while it is possible that other deaths from this rare disease have occurred here, this was the first official indication of its presence in Illinois. The state department indicated that toxoplasmosis will probably be made a reportable disease in Illinois in the near future.

Governor's Conference on Exceptional Children Postponed.—Plans for the third annual Governor's Conference on Exceptional Children, to be conducted by the Illinois Commission for Handicapped Children the latter part of February, have been changed in compliance with the general request recently issued by the Office of Defense Transportation. The date of the conference has been postponed, perhaps for a few months, perhaps for the duration of the war.

Health at Southern Illinois Normal.—Cold prevention week was observed on January 22-26 for the first time at the Campus Laboratory Schools, Carbondale, consisting of the Allyn Elementary School and the University High School on the campus of the Southern Illinois Normal University, as a part of the general health program carried on at the school. The Southern Illinois Normal University has had for a number of years a cold prevention program, but this is the first time the Campus Laboratory Schools have set aside a week to emphasize the event. Of 190 high school students given the patch test recently, 7 showed a positive reaction and will be given roentgenograms at the expense of the Jackson County Tuberculosis Association and local service organizations. Of 150 students who were given patch tests in the Allyn Elementary School, 10 showed positive reactions. Chest x-rays revealed 1 active case of tuberculosis.

Chicago

Lecture on Hypertension.—Dr. George E. Wakerlin, professor and head of the department of physiology, University of Illinois College of Medicine, lectured on hypertension at the Student Union Building February 2. The lecture was under the auspices of the Phi Delta Epsilon Fraternity.

Alumni Association Adopts Key.—The official key of the Alumni Association of the University of Chicago School of Medicine, recently adopted by action of the executive committee, is an adaptation of a key formerly presented to residents of Billings Hospital. The front entrance of Billings in cameo is on the presenting surface, and the reverse side bears the seal of the University of Chicago, the words "School of Medicine" and the engraved initials and graduation date.

Committee on Internships Named at University of Chicago.—A faculty committee on internships has been appointed at the University of Chicago School of Medicine to assist students in obtaining internships and residencies. Dr. Arthur C. Bachmeyer, chairman, F. Joseph Mullin, Ph.D., secretary, and Drs. Emmet B. Bay, Hilger P. Jenkins, Francis Howell Wright and J. Robert Willson are members of the committee. The facilities of the Medical Alumni Association (*THE JOURNAL*, January 27, p. 235) will be at the disposal of the committee, and Dr. Bay will act as intermediary between the association and the faculty committee. According to the *Bulletin of the Alumni Association* it is expected that the members of the association on staffs of hospitals in various parts of the country will be called on to assist in securing appointments for University of Chicago students to the best advantage of both the student and the hospital.

INDIANA

Physician Gives Library to Franklin College.—Before his death, December 10, Dr. William P. Garshwiler, Indianapolis, presented his library to Franklin College, Franklin, in memory of his wife, Florence Province Garshwiler, and her brother, Dr. Clarence Province, both of whom and Dr. Garshwiler had attended Franklin College. Dr. Province died in 1931.

Marcelle Award Goes to Mary Loveless.—The Marcelle Award with its cash prize of \$350 has been awarded to Dr. Mary E. H. Loveless, New York, by the annual forum on allergy for her attempt "to correlate thermostable antibodies with clinical results and the consequent use of 'booster doses,' which may well shorten and simplify our treatment of hay fever." The second Marcelle Prize, of \$150, went to Dr. Charles F. Code of the section on clinical physiology, Mayo Foundation, Rochester, Minn., for his "studies of the role of histamine in the production of anaphylactic and allergic reactions." Dr. Arnold R. Rich of the Johns Hopkins University School of Medicine, Baltimore, and his associates received honorable mention for their work on serum sickness and periarteritis, as did Dr. Frank A. Simon, Louisville, Ky., for his studies of the allergens in human dander.

UNRRA Takes Over World Health Duties.—The functions of the International Office of Public Health in Paris will be performed by the United Nations Relief and Rehabilitation Administration for a limited period under two sanitary conventions concerning maritime and aerial travel, it is reported. The conventions, signed by the state department January 5, will come into force when signed or acceded to by ten or more governments and will run for not more than eighteen months after they have become effective. Signature by the United States was made "subject to ratification," the New York Times reported. After the signature of four governments, France, Great Britain, Poland and the United States, the conventions were then left open for other signatures, after which time they were to be open to accession by any government. They amend the international maritime sanitary convention of 1926 and the international sanitary convention for aerial navigation of 1933 to confer the duties on UNRRA so that its efforts may be facilitated in the fields of displaced person and epidemic control.

Fellowships for the Training of Health Officers.—The Commonwealth Fund of New York through its division of public health is offering a group of fellowships for the training of health officers. All applicants must possess a medical degree, have had at least one year's internship and have shown ability together with interest in and aptitude for public health, with preference going to men who have had at least a few months experience in actual public health work. A total of six fellowships will be available, the stipends being distributed as follows:

Single men—\$175 to \$200 a month, depending on circumstances, plus tuition and travel from home to school, and return.

Married men—\$200 to \$250 a month, depending on individual circumstances, plus tuition and travel from home to school and return.

Application blanks and accompanying papers must be filed with the Commonwealth Fund, which reserves the right to require personal interviews if it is deemed necessary. Awards made by the fund will be subject to acceptance by the school of public health concerned. Schools at which these fellowships will be tenable are:

Johns Hopkins University School of Hygiene and Public Health, Baltimore.

School of Public Health of the University of Michigan, Ann Arbor.

DeLamar Institute of Public Health of Columbia University, New York.

Graduate School of Vanderbilt University, Nashville, Tenn.

School of Public Health of the University of North Carolina, Chapel Hill.

March of Dimes Extended.—The Miracle of Hickory. —Because numerous motion picture houses throughout the country were closed during the March of Dimes Week, January 25-31, on account of the critical fuel situation, the campaign was extended to February 15 to permit additional contributions to the National Foundation for Infantile Paralysis. Coincident with the annual appeal for funds in various public endeavors was the release of a motion picture trailer entitled "The Miracle of Hickory," written and directed by Frank Whitbeck of the Metro-Goldwyn-Mayer Pictures, Culver City, Calif., who created all the previous March of Dime trailers. The film tells briefly the story of the poliomyelitis epidemic that struck Hickory, N. C., last summer and has been released through the National Screen Service. Greer Garson again makes her appearance in the trailer this year, having made similar successful requests in the trailers for 1943 and 1944. The picture depicts the development of the Emergency Infantile Paralysis Hospital—"The Miracle of Hickory," a small summer camp for patients, fifty-four hours later.

Among others to contribute to the National Foundation for Infantile Paralysis for its quick response for aid, Dr. Carl V. Reynolds, state health officer, Dr. A. Gaither Hahn, chairman of the Catawba County chapter of the national foundation, Dr. Harold C. Whims, county health officer, Dr. Robert L. Bennett Jr., director of physical medicine at the Georgia Warm Springs Foundation, Dr. Edward A. Piszczek, Chicago, and Col. Frank Wilson, M. C., commanding officer of the Moore General

Hospital, who supplied, among other things, 40 urgently needed beds. Credit is also given to the American Red Cross and local business authorities who supplied immediate services of all types. The film shows that, when the Hickory Emergency Infantile Paralysis Hospital opened its doors fifty-four hours after the idea was conceived, workmen were still busy in one ward as the children were placed in the other. Units of the state guard voluntarily spent their Sundays working around the hospital, clearing brush from the grounds, doing odd chores; other local residents cooperated in sundry tasks; and 32 women prisoners were paroled by the governor to ease the load of hospital housework. Pictorially the film describes the great good accomplished by the annual March of Dimes of the National Foundation for Infantile Paralysis. In 1944 the national movie total for the fight against infantile paralysis was \$4,667,000. The National Foundation News acknowledges with thanks the efforts of Mr. Whitbeck and the cooperation of National Screen Service.

Football Fatalities.—There were 17 deaths attributed directly to football during 1944, 1 of them the first college football fatality since 1940, newspapers reported January 13. The total number was 6 more than in 1943 but was 14 under the peak of 31 in 1931, when the first of the surveys of this group of deaths was made by Frank S. Lloyd, Ph.D., then at New York University, and Fielding H. Yost of the University of Michigan, Ann Arbor. Five deaths were among players on sand lot teams, 2 on athletic club teams and 9 in high schools. The most frequent cause of death was cerebral hemorrhage. In a report to the National Collegiate Athletic Association, Floyd R. Eastwood, Ph.D., professor of physical education for men, Purdue University, Lafayette, Ind., stated that "the head still has not been adequately protected against injury in light of the continually increasing number of these injuries." The report listed halfbacks as occupying the most hazardous position. Fatalities at this spot made up 18.8 per cent of the total. Others were ends 11.7 per cent, tackles 7.4 per cent, fullbacks 6.6 per cent, quarterbacks 5.5 per cent and guards 5.1 per cent. Injuries suffered making tackles accounted for 30.8 per cent of the fatalities. The next most frequent cause was blocking, with 10.2 per cent. Dr. Eastwood said the survey showed that most of the fatal injuries still occur in the second and fourth periods of games, which appears still a further reason for more frequent substitutions.

Government Services

Group to Study Illegitimacy Problem

A National Advisory Committee on unmarried parenthood is being formed by Katharine F. Lenroot, LL.D., chief of the Children's Bureau, U. S. Department of Labor, the New York Times reported January 3. "It is not merely a matter of a growing wartime illegitimacy rate," Miss Lenroot is reported to have said, "it is also a matter of not enough social workers, not enough medical and social service facilities available, not enough public information on the resources that are available."

Seek Laws to Curb "Baby Brokers"

A draft of essentials for adoption laws and procedures, which would curb the baby broker business by making every child up for adoption a charge of the state through its welfare department, was issued January 21 by the U. S. Children's Bureau, the New York Times reports. In a statement to the press, Katharine F. Lenroot, LL.D., chief of the bureau, is reported to have said that not more than one fourth of the states had adoption laws which approximated the recommended standards. To end a black market in babies, it was stated, three fourths of the states would need to make changes in methods of dealing with adoption cases, an estimated half of which involved children born out of wedlock. The census bureau receives reports of about 80,000 children born out of wedlock annually, exclusive of ten states which do not include an illegitimacy item on birth certificates. Among the non-reporting states are three of heavy populations, New York, Massachusetts and California. The proposed safeguards would serve:

To protect the child from unnecessary separation from parents who might give him a good home if sufficient help was available, from being adopted by persons unfit to rear him and from interference if he was established in his adoptive home.

To protect the natural parents from hurried decisions to give up a child, made under special strain and anxiety.

To protect adopting parents from taking responsibility for children about whose heredity or physical or mental capacity they knew nothing and from later disturbance of their relationship to the child by natural parents.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Jan. 13, 1945.

The Psychology of British Prisoners of War

In the correspondence columns of the *British Medical Journal* a physician wrote recently that "the very large majority of our returned prisoners of war will be problems for their lifetime." This statement has aroused the astonishment of Major D. L. Charters, whose experience renders him an authority on the psychology of prisoners of war. A Liverpool ophthalmic surgeon, in the Greek campaign of 1941 Major Charters allowed himself to be captured while attending the badly wounded, and with the same humanitarian motive he has since declined two opportunities for repatriation. For the last three and one-half years he has administered the medical affairs of large groups of wounded and disabled prisoners in Germany, including prisoners who are totally blind, have amputated limbs, are extensively burned, are paralyzed and have major orthopedic injuries. Nearly all have known several years of captivity; nearly all have suffered bitter disappointment when the first attempt at repatriation broke down in October 1941 and instead of going home they were returned to prison camps.

Major Charters realizes the pressing psychologic problems which in certain cases have resulted from years of enforced idleness, monotony, physical suffering and disablement. If any group of prisoners of war was likely to present psychologic problems, it was the kind of group with which he has had to deal. Nevertheless he emphatically denies that anything approaching a majority of prisoners will be "problems for their lifetime." Rather he would say that the majority of these men have gained in tolerance, understanding, patience, forbearance and courage. They have acquired a bigger concept of comradeship and community life. The average prisoner has demonstrated a high standard of adaptability and will do so again when he returns home. The average prisoner is not a "problem" to himself, to his companions or to his future employer, Major Charters states.

Poisoning by Petrol Fumes

In the *Journal of the Royal Army Medical Corps* Major T. N. Rudd has described a form of petrol poisoning which has occurred under war conditions. In the earlier phases of the war petrol was dispatched overseas in 4 gallon cans made of thin metal, packed in cardboard cases and stacked in the holds of freight ships. Unfortunately the cans were insufficiently rigid to prevent collapse under their own weight of those at the bottom of the stack, and petrol often escaped into the hold, sometimes to a depth of 2 or 3 feet. At the overseas port men worked intermittently in the holds in short shifts, no apparatus for breathing oxygen being available. A man might work twice a week on petrol shifts of five hours each. He would breathe the petrol laden atmosphere for up to ten minutes, after which he would rest for twice that period on deck, while two successive gangs of his fellows took over. On intervening days he would be employed in a petrol free atmosphere. But military circumstances often necessitated more frequent exposure.

Minor symptoms, such as dizziness, headache, tinnitus and faintness or a sense of intoxication, as from alcohol, were almost constant. Collapse with loss of consciousness frequently occurred. As many as 7 men out of 12 in one gang were rendered unconscious in one five hour shift. Some men were overcome so quickly by the fumes that they were unable to reach the bottom of the hold. On removal to a normal atmos-

phere recovery was immediate, both in stuporous and in exhilarated men. Vomiting was frequent. An unpleasant taste remained in the mouth for hours. Some men were unfit for work for twenty-four to forty-eight hours. These symptoms were transient and were outweighed by more lasting changes. A previously cheerful man became morose and sullen. One man, previously normal, had an acute psychosis. Major Rudd holds that the only satisfactory way to avoid dangerous exposure to petrol fumes of workers in ships' holds is the use of an oxygen apparatus on the worker's back. These should be provided if it should ever again become necessary to export petrol in the manner described.

The Limitations of Penicillin

Delivering the first Lister lecture of the Society of Chemical Industry at Edinburgh, Sir Alexander Fleming, the discoverer of penicillin, said that like the sulfonamides penicillin is highly specific, affecting certain microbes but having little or no action on others. He thought it unlikely that we should ever get an antiseptic which would affect all microbes without being poisonous to some human cells. Thus we shall have to arm ourselves with a series of chemicals covering the whole range of microbe growth. In another respect penicillin is not perfect, Dr. Fleming said; it is rapidly destroyed in the stomach and so is ineffective when taken by mouth. But there is still hope that chemists may be able to synthesize it and then tinker with the molecule so as to remedy imperfections. Moreover there are thousands of other microbes which may manufacture antiseptics even better than penicillin or which may give a clue to the chemical linkages responsible for the destruction of bacteria. "The work is not finished. It is just beginning," he declared.

Honor for South African Surgeon

The honorary fellowship of the Royal College of Surgeons of England has been conferred on I. W. Brebner, professor at Witwatersrand University, South Africa, where he has held the chair of surgery for the last fifteen years. The diploma was handed to him by Major Gen. P. H. Mitchiner, a member of the council of the Royal College of Surgeons, after he delivered the Beyers memorial lecture. He referred to Professor Brebner's work as a surgeon and as a teacher and to the valuable services he had rendered the army in the last war and in this one as consulting surgeon to the South African forces. The fame of that work had spread throughout America and the British commonwealth of nations, General Mitchiner declared.

Marriages

BENJAMIN ELY COLE JR., Mountain Lakes, N. J., to Miss Jennifer Elsie Habian at Camp Le Jeune, N. C., November 29.

BERNADINE DREWNIAKY, Lyndhurst, N. J., to Mr. John Joseph Killeen of Belleville in Taunton, Mass., November 25.

WILLIAM L. MUSSER, Clarksburg, W. Va., to Miss Jeanette Elizabeth Whited in Portsmouth, Va., November 17.

JOHN D. CHRISTIAN, Rocky Mount, N. C., to Miss Virginia Rupprecht of New Brunswick, N. J., November 25.

THOMAS BENEDICT CLARK, Hasbrock Heights, N. J., to Miss Jane Norma Benjamin of Rutherford, December 16.

WILLIAM SPENCER MACCOMB, New York, to Miss Janet Abbot Judd of Middletown, Conn., December 30.

LESTER WALLACE CUNNINGHAM to Miss Gertrude Jessie Reid, both of Mandarin, Fla., November 7.

ROBERT N. BILLS to Miss Garnett Campbell, both of Gary, Ind., in Chicago, October 5.

EVERETT SPERRY BURR to Miss Alice Logan, both of West Chester, Pa., October 17.

SOLOMON J. ROSENBERG, Brooklyn, to Miss Ruth Daniels of Milwaukee, December 31.

JOHN B. TIERNEY, Erie, Pa., to Miss Nell Emmet recently.

Deaths

Irving Samuel Cutter * formerly dean of Northwestern University Medical School and recently health editor of the *Chicago Tribune*, died in the Passavant Memorial Hospital, February 2, aged 69, of carcinoma of the prostate and generalized carcinomatosis.

Dr. Cutter was born in Keene, N. H., Dec. 5, 1875. For a year in 1896 he was instructor in a high school in Humboldt, Neb., principal at the Beatrice High School from 1898 to 1900 and general agent at Ginn and Company from 1900 to 1906. He received the degree of bachelor of science at the University of Nebraska, graduating there in medicine in 1910 and subsequently serving as instructor of physiologic chemistry, professor of biochemistry and director of the laboratory and, for the period 1915 to 1925, as dean. In the latter year he joined the Northwestern faculty as associate professor of medicine and dean, serving in the dual capacity until 1941, when he retired to become emeritus professor of medicine and dean. He had been medical superintendent of Passavant Hospital since 1928, serving also as trustee of Northwestern University and Wesley Memorial Hospital.

Dr. Cutter held the rank of captain in the medical corps of the U. S. Army, 1918-1919, serving in charge of medical service at Camp Gordon, Georgia, and lieutenant colonel in the medical section of the Officers Reserve Corps from 1920 to 1929. He held membership in numerous societies and fraternities, including the American Chemical Society, Sons of the American Revolution, Alpha Omega Alpha, Chi Phi, Sigma Xi and Phi Rho Sigma, of which he had been president from 1927 to 1934. He held fellowship in the American Association for the Advancement of Science and served as chairman, member of the executive council and president in 1923 of the Association of American Medical Colleges. He was president of the Society of Medical History of Chicago in 1934 and at one time was vice president of the Illinois Social Hygiene League. Honorary degrees which he had received included the doctor of science from the University of Nebraska in 1925 and Northwestern University in 1941, and doctor of laws from Jefferson Medical College, Philadelphia, in 1931.

Dr. Cutter was a prolific writer for many years, and served also as first editor of the *Nebraska State Medical Journal* from 1916 to 1918 and member of the editorial board of the *Annals of Medical History*. Since 1934 he had been health editor of the *Chicago Tribune* and author of the daily column "How to Keep Well." In recognition of his services, Col. Robert R. McCormick, editor and publisher of the *Chicago Tribune*, gave property to Northwestern University for the establishment of a fund known as the Irving S. Cutter Fund for Medical Research. Included among his contributions to the literature are *School of Medicine, History of Physical Therapy, History of Obstetrics and Gynecology and Laboratory Manual of High School Botany*, of which he was a co-author.

Logan Clendening * Kansas City, Mo., noted health educator, was found dead in his bed at his home January 31, presumably as the result of suicide, aged 60.

Dr. Clendening was born in Kansas City May 25, 1884. He studied for three years at the University of Michigan, Ann Arbor, but did not complete his studies there because of ill health. In 1907 he graduated at the University of Kansas School of Medicine, Lawrence-Kansas City, entering private practice in Kansas City in 1909. The following year he joined the faculty of his alma mater as instructor in internal medicine, serving in this capacity until 1914; he was assistant professor of medicine from 1919 to 1924 and associate professor of medicine from 1924 to 1928, when he became professor of clinical medicine and history of medicine, a position he held at the time of his death. He was a member of the staffs of St. Luke's and Kansas City General hospitals, serving the two at one time as president of the staff.

Dr. Clendening was a member of numerous scientific groups, including the American Therapeutic Society and the American Climatological and Clinical Association; once he served as president of the American Association of the History of Medicine. He held fellowship in the American College of Physicians, which he had served as a member of the board of governors from 1926 to 1930, third vice president, 1929-1930, and a member of the board of regents in 1931. He had been a major in the medical corps of the U. S. Army in World War I, serving as chief of medical service, Base Hospital, Fort Sam Houston, from 1917 to 1919.

Dr. Clendening for a number of years had written a widely syndicated newspaper column entitled "Diet and Health." Other writings to his credit include *Modern Methods of Treatment, the Human Body, the Care and Feeding of Adults, Behind the*

Doctor, Source Book of Medical History, the Balanced Diet and Laboratory Notebook Method in Teaching Physical Diagnosis and Clinical History Recording. He had traveled extensively in Egypt, England, France, Germany, Greece and Italy and had taken graduate work in Edinburgh.

William M. Donald, Detroit; Detroit College of Medicine, 1887; emeritus professor of medicine at his alma mater, now known as the Wayne University College of Medicine; president of the Wayne County Medical Society, 1922-1923; for many years a member of the council and president in 1928 of the Tri-State Medical Association; past president of the Michigan Health Exposition; member of the American Medical Association; fellow of the American College of Physicians; since 1939 emeritus member of the Michigan State Medical Society, once serving as chairman of its medical section; served as chairman of the Wayne County Board of Review during World War I; served as medical consultant and chief of staff at St. Mary's Hospital, consulting physician for Receiving Hospital and consultant in medicine to Evangelical Deaconess Hospital, St. Joseph's Mercy Hospital and the Jefferson Clinic and Diagnostic Hospital; for many years chief of staff at the Protestant Children's Home; received the honorary degree of doctor of science in medicine from Wayne University in 1935; established the "Doctors' Corner" of the Medical Library, a branch of the Detroit Public Library, in which are books written by physicians on nonmedical subjects and fiction; died in the Grace Hospital December 20, aged 84, of carcinoma of the left side of the urinary bladder.

George Carl Hensel, San Francisco; University of California Medical School, San Francisco, 1922; assistant clinical professor of orthopedic surgery at his alma mater; interned and later on the visiting staff at the University of California Hospital; specialist certified by the American Board of Orthopaedic Surgery, Inc.; member of the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; lieutenant commander, Naval Reserve, not on active duty; for many years on the staff of the Shriners' Hospital for Crippled Children; served as chief surgeon at the Carrie Tingley Hospital, Hot Springs, N. M.; formerly orthopedic surgeon, crippled children's division, Nevada State Department of Health; died November 14, aged 49, of cerebral hemorrhage.

Vernor Milo Moore * Grand Rapids, Mich.; University of Michigan Medical School, Ann Arbor, 1911; served the Michigan State Medical Society as a member of the executive committee and chairman of the council, councilor of the Fifth District and, at the time of his death, president-elect; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, Radiological Society of North America and the American College of Radiology; past president of the Kent County Medical Society; director, x-ray department, St. Mary's Hospital; on the staff of Blodgett Hospital; died December 30, aged 58, of coronary occlusion.

Thomas L. Abington, Oakdale, La.; Memphis (Tenn.) Hospital Medical College, 1903; coroner of Sabine Parish for one term and mayor of Oakdale for two terms; died October 13, aged 75, of pneumonia and nephritis.

Roscoe Conklin Adams, Lexington, Ky.; Barnes Medical College, St. Louis, 1898; rating specialist (medical) at the Veterans Administration; served during World War I; died January 3, aged 67, of hypertensive heart disease.

George Campbell Bates * Rushville, Ill.; Harvard Medical School, Boston, 1921; died in Beardstown December 2, aged 55, of cerebral hemorrhage and diabetes mellitus.

David Takeji Betsui * Hanapepe, Hawaii; Washington University School of Medicine, St. Louis, 1931; diplomate of the National Board of Medical Examiners; served an internship at the Evangelical Deaconess Home and Hospital and the Alexian Brothers' hospitals, St. Louis; lieutenant in the medical reserve corps, U. S. Army, not on active duty; died in the Queen's Hospital, Honolulu, October 24, aged 41, of coronary heart disease.

Aaron Brav * Philadelphia; Medico-Chirurgical College of Philadelphia, 1902; chief ophthalmologist at the Jewish and Northern Liberties hospitals; died December 2, aged 69, of heart disease.

Oliver Wendell Brown * Falmouth, Ky.; University of Louisville Medical Department, 1906; died in the Booth Memorial Hospital, Covington, December 1, aged 70, of carcinoma of the colon at the rectosigmoid junction.

Lillian M. Burlingame, Brooklyn; New York Medical College and Hospital for Women, Homeopathic, New York, 1909; formerly adjunct professor of gynecology at her alma mater; died in the New York Hospital December 4, aged 73, of general abdominal carcinomatosis and arteriosclerotic heart disease with mitral insufficiency.

Marcus F. Carson, Griffin, Ga.; Medical Department of Tulane University of Louisiana, New Orleans, 1894; member of the American Medical Association; formerly a member of the state board of medical examiners; died November 26, aged 73, of cerebral hemorrhage.

William S. Charles * Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1901; died in Chicago October 8, aged 77.

Charles Cleveland Clark, Union City, N. J.; New York Homeopathic Medical College and Hospital, New York, 1898; member of the American Medical Association; on the courtesy staff of the Christ Hospital, Jersey City, where he died November 29, aged 75, of cerebral thrombosis.

Ernest E. Couch, West Allis, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1899; member of the American Medical Association; died November 14, aged 80, of cardiorenal disease and senility.

Raymond John Dawson * Methuen, Mass.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1933; on the courtesy staffs of the Clover Hill and Lawrence General hospitals, Lawrence, and the Mary E. McGowan Memorial Hospital; died November 20, aged 38, of coronary occlusion.

Charles Leo Dugan, Cincinnati; Georgetown University School of Medicine, Washington, D. C., 1912; assistant medical examiner for the Baltimore and Ohio Railroad; died in the Cincinnati General Hospital November 28, aged 55, of a fractured skull and an intracranial hemorrhage.

Fred August Eickelberg, Reeseville, Wis.; Rush Medical College, Chicago, 1902; died November 24, aged 68, of carcinoma of the rectum.

Warren Harkness Everett, Peru, N. Y.; Albany Medical College, 1899; member of the American Medical Association; health officer and school physician; on the staff of the Physicians Hospital, Plattsburg; died December 20, aged 76, of pernicious anemia.

Richard William Finley, Chapel Hill, N. C.; Western Reserve University Medical Department, Cleveland, 1918; formerly on the faculty at his alma mater and on the staff of the Lakeside Hospital in Cleveland; died November 28, aged 54, of heart disease.

John G. Franken, Chandlerville, Ill.; College of Physicians and Surgeons, Chicago, 1895; member of the American Medical Association; died in the Memorial Hospital, Springfield, November 26, aged 81, of interstitial nephritis.

Louis Clark French, Chicago; Illinois Medical College, Chicago, 1905; member of the American Medical Association; died November 20, aged 66, of congestive heart disease and bronchiectasis.

Frederick Julius From, Halbur, Iowa; State University of Iowa College of Medicine, Iowa City, 1887; died in North Loup, Neb., November 21, aged 83, of heart block.

Henry Lisle Gamble, Moorefield, W. Va.; University of the South Medical Department, Swannec, Tenn., 1899; died in the Potomac Valley Hospital, Keyser, November 30, aged 70, of cerebral hemorrhage.

John Reeves Gamble, Lincolnton, N. C.; University of Tennessee College of Medicine, Memphis, 1911; member of the draft board during World War I; served two terms as mayor of Lincolnton; one of the founders and past president of the Rotary Club; chief surgeon for the Seaboard and Southern Railways; member of the American Medical Association; founder, chairman of the staff and medical superintendent of the Reeves Gamble Hospital, where he died December 1, aged 59.

John Simpson Gordon * Milwaukee; University of Illinois College of Medicine, Chicago, 1912; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past president of the Milwaukee County Medical Society; on the staffs of the Milwaukee, Columbia and Children's hospitals; died December 6, aged 56, of coronary occlusion.

Walter A. Hall, New Albany, Ind.; Hospital College of Medicine, Louisville, Ky., 1904; member of the American Medical Association; for many years county physician; on the staff of St. Edward Hospital, where he died December 9, aged 64, of coronary heart disease.

Reuben Caldwell Hanchett, Chicago; Syracuse University College of Medicine, 1884; formerly professor of materia medica and therapeutics at his alma mater and physician to the Hospital of the Good Shepherd in Syracuse, N. Y.; served during World War I; captain, medical reserve corps, U. S. Army, not on active duty; died December 15, aged 81, of carcinoma of the left breast with metastases.

Robert S. Hearn, Pinson, Tenn.; University of Tennessee Medical Department, Nashville, 1904; member of the American Medical Association; died in the Gantly-Ramsay Hospital, Memphis, December 9, aged 69, of bronchopneumonia.

John Ernest Heiss, Perry, Okla.; Loyola University School of Medicine, Chicago, 1916; member of the American Medical Association; died December 14, aged 60, of heart disease.

Gustav A. Hermann * Hamilton, Ohio; Western Pennsylvania Medical College, Pittsburgh, 1896; member of the board of health; died in Indianapolis December 7, aged 80, of coronary thrombosis.

Hardin I. Hughes, Hardin, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1901; died December 5, aged 69, of arteriosclerosis.

Thomas Charles Irwin * Grand Rapids, Mich.; Trinity Medical College, Toronto, Ont., Canada, 1891; served as president of the Kent County Medical Society; formerly professor of surgery and clinical surgery at the Grand Rapids Medical College; on the courtesy staffs of the Butterworth and St. Mary's hospitals; from 1924 to 1928 chief of staff, Blodgett Memorial Hospital, where he died December 9, aged 78, of coronary thrombosis.

John Russell Kelly, Plainfield, N. J.; University of the City of New York Medical Department, New York, 1892; for many years a physician with the Holland-American Steamship Line; died December 24, aged 75, of coronary thrombosis.

Joseph W. Kemp, Roanoke, Ind.; Medical College of Indiana, Indianapolis, 1891; died November 29, aged 88, of pneumonia, influenza and cerebral hemorrhage.

Louise Cora Kralick, Pittsburgh; University of Pittsburgh School of Medicine, 1930; died November 24, aged 44, of angina pectoris.

Walter Max Kraus * New York; Johns Hopkins University School of Medicine, Baltimore, 1913; member of the American Neurological Association, American Association of Neuropathologists and the Association for Research in Nervous and Mental Disease; served during World War I; commissioned a major in the medical corps, Army of the United States, on April 29, 1943; resignation from service effective in April 1944; died August 18, aged 55.

John Leonard Lee * Alexandria, Minn.; University of Minnesota Medical School, Minneapolis, 1922; interned at the Minneapolis General Hospital; died in Minneapolis December 9, aged 49, of coronary occlusion.

Marquis H. Maness, Roxton, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1882; member of the American Medical Association; died in Terrell November 21, aged 85, of senility.

Benjamin Franklin Markin, Columbia, S. D.; Columbian Medical College, Kansas City, Mo., 1900; died October 6, aged 65, of coronary thrombosis.

Harry E. Matthews * Orange, N. J.; College of Physicians and Surgeons, New York, 1888; served during World War I; on the staff of the Orange Memorial Hospital; died in Bermuda November 25, aged 78.

William J. McCarthy, Madelia, Minn.; Northwestern University Medical School, Chicago, 1897; member of the American Medical Association; in 1920 president of the Southern Minnesota Medical Association; president of the board of education at Madelia for many years; also served as mayor of Madelia and chairman of the board of health; owned and operated the Madelia Hospital from 1918 to 1941, when it was purchased by the village; bank president; died October 25, aged 76, of acute lymphatic leukemia.

Robert Howard Meikle, Arlington, Mass.; University of Bishop College Faculty of Medicine, Montreal, 1897; died October 12, aged 73, of pulmonary edema.

William Wallace Noyes, Dunbar, W. Va. (licensed in West Virginia in 1903); died in Cumberland, Md., December 15, aged 74, of chronic bronchial asthma, general arteriosclerosis and chronic myocarditis.

Arcadio Tigrio Obando, Los Angeles; Cornell University Medical College, New York, 1930; member of the American Medical Association; interned at the Hollywood Clara Barton Memorial Hospital; died November 5, aged 41, of contusion of the brain and subdural hemorrhage.

Daniel Adam Orth * Wheaton, Ill.; Rush Medical College, Chicago, 1896; fellow of the American College of Surgeons; at one time clinical professor of surgery at the Loyola University School of Medicine, Chicago; formerly secretary and since 1912 attending surgeon at St. Mary of Nazareth Hospital,

Chicago; president and chief of surgical staff, Columbus Hospital, Chicago, where he died January 3, aged 72, of left bundle branch block.

Jeddiah William Pidcock * Los Angeles; College of Physicians and Surgeons of San Francisco, 1907; formerly practiced in Ogden, Utah, where he served as county physician and was on the staff of the Thomas D. Dee Memorial Hospital; on the staff of the Hollywood Hospital; died October 30, aged 66, of nephritis and diabetes mellitus.

William H. Porter, Calvin, N. D.; College of Physicians and Surgeons, School of Medicine of the University of Illinois, 1903; served as state senator; died in the General Hospital, Devils Lake, October 15, aged 71, of carcinoma of the rectum.

Linley Murray Reagan, Kokomo, Ind.; Physio-Medical College of Indiana, Indianapolis, 1901; served during World War I; formerly professor of obstetrics at his alma mater; died November 28, aged 72, of coronary embolism.

Jacob Michael Smittle, Waucoma, Iowa; State University of Iowa College of Medicine, Iowa City, 1897; formerly member of the state board of health, school board and town

tendent of the Washington County Hospital; visiting surgeon at the Barre City Hospital; died November 11, aged 63, of accidental illuminating gas poisoning.

Arthur Henry Temple * Passaic, N. J.; Columbia University College of Physicians and Surgeons, New York, 1896; served in France during World War I; chief of staff, Passaic General Hospital; died in Greenwood Lake November 16, aged 70, of coronary occlusion.

Jesse Harold Turner, La Canada, Calif.; Loyola University School of Medicine, Chicago, 1927; member of the American Medical Association; interned at St. Luke's Hospital in San Francisco; on the staff of the French Hospital, Los Angeles; died November 20, aged 48, of coronary occlusion.

Frank Vanatta Willhite, Redfield, S. D.; College of Physicians and Surgeons, School of Medicine of the University of Illinois, 1905; member of the American Medical Association; since 1923 medical superintendent of the State School and Home for Feeble-minded; died October 20, aged 66, of carcinoma of the rectum.

Tazwell Brown Wingo, Martin, Tenn.; Vanderbilt University School of Medicine, Nashville, 1900; died in the Baptist

CAPT. HERMAN L. JACOBUS
M. C., A. U. S., 1916-1944

CAPT. EDWARD J. HACKETT
M. C., A. U. S., 1907-1944

MAJOR MICHAEL A. RAFFERTY
M. C., A. U. S., 1903-1944

council; on the staff of the Decorah Hospital, Decorah; died in St. Joseph's Hospital, New Hampton, November 19, aged 69, of arteriosclerosis, prostatic hypertrophy and bronchopneumonia.

John William Stewart * Barre, Vt.; University of Vermont College of Medicine, Burlington, 1907; acting superin-

tendent of the Washington County Hospital; died November 10, aged 71, of congestive heart disease due to coronary insufficiency and diabetes mellitus.

Thomas Grant Youmans, Columbus, Ohio; Starling Medical College, Columbus, 1895; professor of genitourinary surgery and dermatology at the Ohio Medical University from 1899 to 1901; police surgeon for eight years; died October 18, aged 75.

KILLED IN ACTION

Herman Lawrence Jacobius, New York; Cornell University Medical College, New York, 1939; served an internship at the Mount Sinai Hospital, New York, and a residency in medicine at the Montefiore Hospital, New York; commissioned a first lieutenant in the medical corps, Army of the United States, on Oct. 3, 1942; later promoted to captain; took part in the North African campaign and the invasion of Sicily and Italy; killed in action in the Netherlands Sept. 28, 1944, aged 28.

Edward John Hackett * Westfield, N. J.; University and Bellevue Hospital Medical College, New York, 1933; interned at the Medical Center of Jersey City; formerly police surgeon; served as medical inspector of the public schools and of Holy Trinity schools; commissioned a first lieutenant in the medical corps, Army of the United States, on Aug. 3, 1942; later promoted to captain; squadron surgeon with a mechanized cavalry reconnaissance unit attached to General Patton's Third Army; died in France Sept. 13, 1944, aged 37, of wounds received in action.

Michael Alphonse Rafferty * Weston, W. Va.; Rush Medical College, Chicago, 1937; graduated as a pharmaceutical chemist from West Virginia University in 1929; served an internship at St. Luke's Hospital in Cleveland; formerly associate professor of biochemistry at the West Virginia University School of Medicine, Morgantown; served as assistant medical director of Miles Laboratories, Inc., Elkhart, Ind.; member of the Indiana State Medical Association; commissioned a captain in the medical corps, Army of the United States, on June 2, 1942 and assigned to Billings General Hospital, Fort Benjamin Harrison; in October 1942 began a twelve week course at the University of Michigan to qualify as head of a hospital station laboratory, and in the spring of 1943 was assigned to the station hospital at Fort Custer, Mich., later transferred to Fort Dix, New Jersey, where he was assigned to the 15th General Hospital; promoted to major on Nov. 1, 1943; killed in action in Belgium, Nov. 24, 1944, aged 40.

Correspondence

APPRAISAL OF NEW DRUGS

To the Editor—The communication of Chauncey D. Leake and his associates (*THE JOURNAL*, January 27, p. 244) discussing our recent article "The Laboratory and Clinical Appraisal of New Drugs" (*THE JOURNAL*, Dec. 9, 1944, p. 958) deserves comment, since there are some real differences of opinion regarding some of our proposals. Our paper was concerned not only with setting forth techniques to be used in the investigation of new drugs but also with the establishment of criteria whereby laboratory and clinical data can be evaluated. We included suggestions regarding the type of study which in our opinion would be productive of useful information. As we indicated, however, these suggestions are by no means exhaustive.

We pointed out, as has Professor Leake, that selection of suitable experimental animals is a very important consideration in the laboratory evaluation of new agents. Professor Leake has emphasized the importance of a study of the toxicity of the drug and we agree with this emphasis. We do believe, however, that, in order to approach a study of toxicity effectively, a careful pharmacodynamic study of the drug is essential. Such a study will provide information regarding probable, and often otherwise unsuspected, sites of potentially harmful action.

We are very much concerned with Professor Leake's characterization of long term chronic toxicity studies as "pointless." In opposition to this point of view may we cite the experience of the Division of Pharmacology of the Food and Drug Administration, where during the past four or five years long term chronic toxicity studies have been conducted on about thirty-five chemical agents. In approximately 20 per cent additional definite pathologic changes occurred after the six to nine month period mentioned by Professor Leake and his associates. In all but one instance these late changes involved neoplastic growth. We are therefore very strongly of the opinion that the toxicity of a chemical agent has not been fully appraised until long term studies of this nature have been made.

As Professor Leake has pointed out, chronic toxicity studies may not be necessary for agents which are not used frequently or continuously. Obviously it is 'pointless' to do a long term chronic toxicity study on a diagnostic agent which may be used only once in a person's lifetime.

We should like to insert a note of caution regarding the recommendation to let the knowledge of the toxicity and actions of a group of chemical agents influence the decision as to the extent of work necessary to appraise adequately another closely related agent. The pharmacologic properties of drugs cannot be predicted reliably on the basis of a chemical similarity to other well known drugs. Even optical isomers show tremendous differences in pharmacologic activity, e. g. d- and l-epinephrine and d- and l-amphetamine. Certainly the pharmacologic differences between these four closely related compounds cannot be predicted on the basis of chemical differences alone. True, a knowledge of chemical differences and similarities is valuable as a guide, but there are so many exceptions to the so called relationship between chemical structure and pharmacologic activity that reliance on that relationship as a short cut to adequate investigation is extremely risky.

Finally, we seriously doubt that the application of the criteria set forth in our paper will delay the use of worthwhile therapeutic agents. In fact it is our belief that ill conceived and poorly executed investigations have contributed materially to delays in the proper and widespread use of therapeutically desirable agents.

CHILDREN'S BUREAU STATEMENT ON CRIPPLED CHILDREN PROGRAM

To the Editor—In the Dec. 30, 1944 issue of *THE JOURNAL* page 1154, there is an editorial comment on the recent regulation by the Secretary of Labor relating to provision of diagnostic services under state plans for services for crippled children. In view of the fact that the next to the last sentence misinterprets the regulation and implies that the regulation applies to therapeutic as well as to diagnostic services, I would like to request that the following statement issued by the chief of the Children's Bureau on Dec. 26, 1944 to the executive officers of state crippled children's agencies be made available to the readers of *THE JOURNAL* together with this letter. The statement is as follows:

MEMORANDUM

Dec. 26, 1944

To: Executive officers of state crippled children's agencies
From: Katharine F. Lenroot, Chief, Children's Bureau, U. S. Department of Labor
Subject: Issuance of regulation promulgated by Secretary of Labor pertaining to eligibility requirements for diagnostic services under

The policy set forth in the secretary's regulation does not represent any departure from policies usually followed in comparable public programs of medical care. In many states, for example, services and facilities for the diagnosis of tuberculosis are available to any one who applies for such service. Similarly, medical diagnosis is made freely available to any one who applies for services under state vocational rehabilitation programs. The Rules and Regulations Governing Allotments and Payments to the States of Venereal Disease Funds provide that "all health departments or clinics receiving funds shall provide facilities for (1) diagnosis and emergency treatment of all patients who apply; (2) continued treatment, consultative advice or opinion for all patients referred by private physicians; and (3) continued treatment for all patients unable to afford private medical care."

It is, therefore, sound public policy that diagnostic services be freely available to any child who applies for services under the state crippled children's program in order that the responsible public agency may determine the need for and extent of care required if the child is to have the best possible physical restoration, emotional and social adjustment, and educational and work opportunities.

The regulation of the Secretary of Labor to which the foregoing statement refers is as follows:

Nov. 25, 1944.

U. S. DEPARTMENT OF LABOR
OFFICE OF THE SECRETARY
Washington, D. C.

Title 42—Public Health

CHAPTER II—U. S. CHILDREN'S BUREAU

Part 202—Services for Crippled Children

Pursuant to the authority granted by section 1102, 49 Stat. 647, 42 U. S. C. 1302; section 513, 49 Stat. 632, as amended by section 506, 53 Stat. 1381, 42 U. S. C. 713, the following amendment to section 202.4 of the regulations (42 C. F. R. part 202) relating to services for crippled children is herewith issued:

Section 202.4 is amended by inserting, after the second sentence thereof, the following provisions: "Effective July 1, 1945, it shall be a condition of approval of a plan that it provide that diagnostic services will be made available thereunder to crippled children without restrictions as to race, color, creed, economic status, legal residence, age (except as to persons above the maximum age for which such services are legally available within the state), the necessity of referral by any person other than the child's parents or legal guardian, or similar restrictions inconsistent with the free availability of such services." (Sec. 1102, 49 Stat. 647, 42 U. S. C. 1302; Sec. 513, 49 Stat. 632, as amended by Sec. 506, 53 Stat. 1381, 42 U. S. C. 713.)

Nov. 17, 1944.

Approval recommended.

FRANCIS PERKINS.

Secretary.

KATHARINE F. LENROOT,
Chief of the Children's Bureau.

(seal)

I hereby certify that this is a true copy of the original.

PETER SEITZ,
Principal Attorney.

MARIHA M. ELIOT, M.D., Washington, D. C.

Associate Chief, Children's Bureau,

U. S. Department of Labor.

NEUROMUSCULAR EXHAUSTION SYNDROME

To the Editor:—I was greatly interested in the paper "A Subacute Generalized Neuromuscular Exhaustion Syndrome" by J. M. Nielson, in THE JOURNAL, Nov. 25, 1944, page 801. A possible etiologic explanation for this "syndrome" is that it represents acute beriberi (i. e., acute polyneuritis). It could be explained on the basis of exhaustion of vitamin B by the heightened metabolism of excessive physical exertion in the face of a relatively inadequate supply of that vitamin.

As pointed out by G. R. Cowgill (The Vitamin B Requirement of Man, New Haven, Conn., Yale University Press, 1934) any process increasing the total metabolism will increase the requirement for vitamin B.

I reported (case 7 in Vitamin B Deficiency in Private Practice, *New England J. Med.* 231:174 [Aug. 3] 1944) a slightly similar though very much milder case of peripheral neuritis of the nerves of the arms and hands of a former shipyard worker who did heavy manual labor from sixteen to seventeen hours a day.

The importance of recognizing the nature of the underlying process as essentially a simple vitamin B deficiency lies, of

course, in the obvious therapeutic implications. Untreated peripheral neuritides, even those proved to be due to deficiency of vitamin B, eventually become refractory to all therapy. Time is of the greatest importance. Early neuritis of this type responds dramatically to appropriate therapy.

DUDLEY MERRILL, M.D., Cambridge, Mass.

TRANSITORY PULMONARY INFILTRATIONS

To the Editor:—The editorial "Transitory Pulmonary Infiltrations Associated With Eosinophilia—Loeffler's Syndrome," which appeared in THE JOURNAL, Nov. 25, 1944, was a most interesting summary of a condition that seems to have suffered unmerited neglect. In discussing the possible etiologic role played by parasites, reference was made in the editorial only to *Ascaris lumbricoides*, *Fasciola hepatica* and *Endameba histolytica*. Transient pulmonary infiltrations are known to occur in patients infected with *Necator americanus* and, possibly even more commonly, in patients infected with *Strongyloides stercoralis*.

Pulmonary changes associated with strongyloidiasis are well appreciated in animals (Blacklock, B., and Adler, S.: The Pathological Effects Produced by Strongyloides in a Chimpanzee, *Ann. Trop. Med.* 16:283 [Oct.] 1922. Faust, E. C.: Experimental Studies on Human and Primate Species of Strongyloides: IV. The Pathology of Strongyloides Infection, *Arch. Path.* 19:769 [June] 1935. Lecarpentier-Dubosq, M.: La strongylose broncho-pulmonaire des bovidés: Traitement et prophylaxie, *Ecole nat. vet. d'Alfort*, Paris, 1928. Smith, R. P.: Pulmonary Strongylosis in Sheep, *Vet. J.*, London 83:294, 1927.) Gage (A Case of Strongyloides Intestinalis with Larvae in the Sputum, *Arch. Int. Med.* 7:561 [April] 1911) reported a case in which there were signs of diffuse bronchitis and lobar pneumonia and, in the sputum, Strongyloides larvae. The process in the lungs cleared rapidly, although the larvae persisted in the sputum for two months. At postmortem examination the diagnosis of Strongyloides pneumonitis was confirmed. De Langen (cited by Strong, R. P., in Stitt's Diagnosis, Prevention and Treatment of Tropical Diseases, ed. 6, Philadelphia, Blakiston Company, 1942, vol. 2, p. 1284) described 2 cases of strongyloidiasis in which larvae were recovered from the sputum. In material regarded as sputum mixed with vomitus obtained from a patient whose feces showed large numbers of rhabditiform larvae, Shimura and Ogawa (On Filariform Larvae Found in Vomit of a Patient Infested with Strongyloides, *Tokyo M. News*, 1920, number 2197, p. 1829) found filariform larvae and at autopsy were able to trace the course of migration of the larvae from the intestine to the lungs. Nolasco and Africa (Fatal Case of Paralytic Ileus Associated with Severe Strongyloides Infestation Suggesting Internal Autoinfection, *J. Philippine Islands M. A.* 16:275 [May] 1936) and Torres and De Azevedo (Lesions Produced in Man by Strongyloides, *Livro Jubilar de Prof. L. Travassos*, Rio de Janeiro, 1938, p. 475) demonstrated Strongyloides larvae in the lungs in human beings at autopsy. Froes (Larves de strongyloides dans un épanchement séro-hémorragique de la plèvre, *Ann. de parasitol.* 8:171 [March 1] 1930) reported a case of pleural effusion in which rhabditiform larvae were discovered before death. Yoshino (Clinical Observations on 25 Cases of Strongyloides Stercoralis in the Yaeyana Archipelago, *J. M. A. Formosa* 31:99, 1932) described 25 cases of strongyloidiasis, in 14 of which bronchitis was present. Larvae were found in the sputum of 3 of the latter. Faust (Experimental Studies on Human and Primate Species of Strongyloides: IV. The Pathology of Strongyloides Infection, *Arch. Path.* 19:769 [June] 1935) described the case of a volunteer who was inoculated percutaneously with a chimpanzee strain of strongyloides and who showed both subjective and

objective evidence of slight pulmonary involvement from the fourth to the eighth day after inoculation

It would appear that the transient pulmonary infiltrations which occur in some patients with helminthiasis and eosinophilia, especially in those infected with *Strongyloides stercoralis*, may represent invasion of the lungs by the larvae themselves. At any rate, careful and thorough study of the sputum and the stools for ova and parasites is warranted in every case in which transitory pulmonary infiltrations appear associated with eosinophilia

MEDICOLEGAL ABSTRACTS

Malpractice: Explosion of Bulb in Infra-Red Lamp
—The patient suffered from arthritis and neuritis and at intervals for about four years submitted to infra red treatments administered by the defendant chiropractor in his office. Dec 6, 1940 she lay on a table unattended in a room with her back exposed to an infra-red deep therapy lamp about 30 inches distant, having an unscreened 1,000 watt bulb. After she had been in this position for about fifteen minutes the bulb exploded without warning and hot glass fell on her back causing severe burns. She and her husband instituted an action for malpractice against the chiropractor. At the conclusion of the evidence of the plaintiff at the trial the court granted a motion for nonsuit on the ground that the evidence had failed to prove negligence on the part of the chiropractor. On appeal the district court of appeals, fourth district, California affirmed the action of the trial court. *Croce v McBride*, 149 P (2d) 69 J A M A 125:868 (July 22) 1944. The plaintiffs then appealed to the Supreme Court of California.

In considering the propriety of the nonsuit entered by the trial court, said the Supreme Court we must accept the evidence that is most favorable to the plaintiffs and disregard that which is unfavorable. At the trial the plaintiffs called as a witness the chiropractor who stated that he had made no inspection of the bulb that exploded and could make none other than turning it on to see if it was working that he did not know what caused the bulb to explode, that he had never heard of one exploding before that he had used the bulb in question for approximately two years before the accident that he had a number of the same type which he used as frequently as ten times a day each, that some operated as long as five years before burning out that there are about 200 lamps of this type in use in his locality, that the bulb in question was a standard one in general use, and that no manufacturer so far as he knew, had ever theretofore recommended the screening of such lamps as a precautionary measure. The defendant's evidence, the Supreme Court emphasized, while indicating that the lamp to which the patient was exposed had no screen on it was to the effect that the chiropractor did have screens on the other lamps in use in his office. The plaintiffs contended that the trial court could have reasonably concluded from the evidence that the chiropractor's failure to use a screen or other protective device constituted negligence. In answer to this the chiropractor argued that there was no evidence produced at the trial that he could have used a screen without interfering with the therapeutic efficiency of the lamp or that such a screen would have prevented injury to the patient. The court however, concluded that an effective answer to the defendant's points was the fact that after the injury to the patient he used screens as a protective measure on all lamps in his office. From this said the Supreme Court the trial court could reasonably have inferred that a screen would not have interfered with the therapeutic efficiency of the lamp or that it would have afforded at least some protection in event of damage to the bulb. Furthermore, the court thought it significant that in the brief filed by the defendant on appeal there was a concession that if a screen had been used the injuries to the patient might not have been

so serious, "since only the smaller particles of glass would drop through the screen." The fact remarked the court that an available safety device could not entirely prevent an accident would not, of course excuse the chiropractor from employing it to minimize injuries.

The chiropractor contended that since there was no evidence of any other similar explosions having occurred or that any manufacturer of similar lamps has recommended screens as a precautionary measure he had no reason to anticipate such a fortuity as occurred or to take precautions to avoid it. We cannot hold as a matter of law, said the Supreme Court, that the chiropractor had no duty to take such precautions. We believe that the chiropractor's use of the lamp without a screen presented a question to be determined by the trier of fact on the issue of negligence. Glass articles such as electric light bulbs are fragile and are frequently broken from many and varied causes. The 1000 watt bulb used in this case was an exceptionally large one in comparison with an ordinary light bulb, and it was designed to generate heat. The likelihood of serious injury in the event of breaking whatever the cause, was obvious and was much greater than could be expected from the breaking of an ordinary illuminating bulb. As has often been said the care required must be in proportion to the danger to be avoided and the consequences that might reasonably be anticipated. The trial court might reasonably have concluded that the chiropractor should have anticipated that the bulb might break or be broken and that he did not take the precautions reasonably to be expected to avoid or minimize injury. The fact that the bulb broke or exploded in an unusual manner and that the exact cause of its doing so was unknown may be considered by the trier of fact but it does not necessarily follow that the chiropractor is as a matter of law free from liability. As is said in Restatement, Torts sec 435

If the actor's conduct is a substantial factor in bringing about harm to another the fact that the actor neither foresaw nor should have foreseen the extent of the harm or the manner in which it occurred does not prevent him from being liable.

Furthermore, continued the court, accidents of this type are not entirely unknown, as at least two cases involving explosions of light bulbs have reached appellate courts. See *Hughes v Atlantic City & S R Co* 85 N J Law 212, 89 A 769, L R A 1916 \ 927, *Russell v St Louis & S F R Co*, Mo App, 245 S W 590.

The Supreme Court accordingly held that the evidence with respect to negligence adduced by the plaintiffs at the trial was sufficient to present a question for the trier of fact and that the nonsuit should not have been granted. The judgment of nonsuit was accordingly reversed.—*Croce v McBride* 149 P (2d) 727 (Calif 1944)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Thiouracil in Thyrotoxicosis.—Thirty of 37 thyrotoxic patients observed by Rose and McConnell treated with thiouracil showed a favorable response, 4 a partial response and 2 no response. Three of the 6 patients showing an unsatisfactory response presented associated conditions which may have influenced their reactions. In 4 patients thiouracil was used during preparation for thyroidectomy. One of these died twenty hours after operation, but thiouracil was not regarded as a factor in his death. Necropsy in this case showed no lesions which could be associated with the use of the drug. The control of thyrotoxicosis with thiouracil in a 13 year old girl with diabetes mellitus was not followed by an increase in her carbohydrate tolerance or a decrease in insulin requirement. The microscopic appearance of the thyroid gland in patients prepared for thyroidectomy with thiouracil showed the hyperplasia and other changes previously reported by others. Eight patients have remained in remission for periods varying from three weeks to seven months following the complete withdrawal of thiouracil; on minimal doses 3 patients have responded likewise. Thirteen patients relapsed when the drug was either reduced in dosage or withdrawn; all of these patients again responded to readministration of thiouracil. Measurements of the cardiac output by ballistocardiogram of 9 patients showed a general tendency toward reduction in output under thiouracil therapy which was roughly parallel with the decline in basal metabolism. No evidence of development of refractoriness to thiouracil was observed. Untoward reactions attributable to the drug occurred in 8 cases. The most important of these was neutropenia with pharyngitis and fever, noted in 2 cases. Reduction in the size of the thyroid gland was noted in 8 cases after prolonged treatment. Exophthalmos tended either to remain stationary or to increase slightly. The drug effectively controls most of the phenomena of thyrotoxicosis in the large majority of cases. Its use is justified in the protracted treatment of mild or moderately severe cases and in the preparation of selected patients for thyroidectomy. It may also prove of considerable value for patients regarded as unacceptable surgical risks.

Penicillin in Infections Complicating Diabetes.—Peck reports 15 cases of diabetes which illustrate that penicillin is remarkably efficacious in the infectious type of gangrene, osteomyelitis of the bones of the feet and the huge sloughing car-

buncles. He never noted a deleterious effect on carbohydrate tolerance, nor has penicillin administration necessitated larger doses of insulin. The presence of infection notoriously increases the insulin requirement, but in none of the cases described was there any unusual difficulty.

Sulfamerazine in Meningococcic Meningitis.—Oliver and Anderson report the results obtained with sulfamerazine in 56 cases of meningococcic meningitis. All presented the typical clinical picture of meningitis, and in each case the diagnosis was confirmed by bacteriologic studies. The severity of the illness varied: 13 patients were regarded as mildly ill; in 24 the illness was of moderate severity; 19 were severely ill. The patients in the last group were either comatose or nearly so. A petechial rash was observed in 34 patients. The usual dosage of sulfamerazine employed in the adult group was an initial dose of 2 Gm. orally followed by a maintenance dose of 1 Gm. every eight hours. In children, dosage was calculated on a basis of 1 Gm. to 20 pounds (9 Kg.) of body weight per day. Comatose patients and those who were otherwise too ill or uncooperative to take medications by mouth were given the sodium salt of the drug intravenously. Treatment was continued until the patient had made a clinical recovery. The average duration of treatment was 8.4 days. As far as possible, daily determinations of the whole blood concentration of both the free and the total drug were made in all cases. Fluids were administered liberally. No deaths occurred. Complications of meningitis were observed in 8 cases. Except for 1 case of nerve deafness, the complications had cleared before discharge from the hospital. Except for 1 patient who experienced renal colic, no serious toxic reactions to sulfamerazine were encountered. The authors conclude that sulfamerazine is an effective agent in the treatment of meningococcic meningitis.

Calcification of Cephalhematomas of Newborn Infants.—Cephalhematomas of the newborn infant are localized collections of blood beneath the periosteum of one of the bones of the cranial vault. They may be single or multiple. The entire periosteum covering the cranial bone is elevated. The swelling appears the first or second day after delivery and usually absorbs rapidly after the first week of life. Most of them are completely absorbed by the third week. The common plan of treatment is one of conservatism. An appreciable number calcify, forming a more or less permanent deforming lump on the child's head. While this lump is of importance only from the cosmetic standpoint, it causes the parents great concern. If absorption has not taken place by the end of the second week, the contents have usually liquefied and can be easily aspirated. If a fairly large bore needle is introduced beneath the elevated periosteum, from 10 to 40 cc. of thick bloody liquid can be withdrawn. The cyst then largely collapses; the small amount of remaining contents rapidly absorbs, and permanent deformity is prevented. If an aseptic technic is used, infection does not have to be feared. In the past five years Morgan has routinely aspirated those cephalhematomas which did not absorb rapidly and has had no complications.

Supracervical Pregnancy Following Supravaginal Hysterectomy.—According to Stanley-Brown and Shields, supracervical pregnancy following hysterectomy is a rare occurrence. The authors found reports of 6 cases of pregnancies following hysterectomies, to which they add 1 of their own observation. They report the history of a woman who had given birth to 2 children, 1 in 1934 and 1 in 1938. Later she developed menstrual disturbances, and in 1941 a fibroid was distinguished in the fundus. A hysterectomy was done in June 1943 because the fibroid had enlarged. The uterus was amputated at the uterocervical junction without removing the tubes and ovaries. The cervical stump was closed with four interrupted chromic sutures. The ligated tubes and round ligaments were sutured to the posterior lip of the cervical stump, and the bladder peritoneum was brought over to cover the area. The patient made an uneventful recovery. Following this the patient was well and had fairly regular, scanty monthly bleeding. At a consultation in March she stated that she had missed one period, was nauseated and had occasional lower abdominal pains. Examination in April showed a softer cervix and immediately above it a small, soft mass. The nausea increased and the picture duplicated that of her two previous pregnancies. An exploratory laparotomy was done. The bladder peritoneum was dissected free and laid back. Beneath the fold there appeared tissue which resembled placenta, and from this by blunt dissection a sac of fluid containing a $6\frac{1}{2}$ weeks embryo was shelled out intact. As much placental tissue as possible was removed, and the stump of the cervix was closed with chromic sutures. The patient made an uneventful recovery.

Penicillin Therapy in Ocular Infections.—The concentration in the ocular tissues and fluids after administration of a large intravenous dose of penicillin is listed in decreasing order as follows: extraocular muscles, sclera, conjunctiva, blood, tears, chorioretinal layer, aqueous and vitreous humors and cornea. It has never been detected in the crystalline lens. Local application of penicillin leads to a high concentration of the drug in the tissues of the anterior segment of the globe. The following ointments in which the penetrability of penicillin was tested are listed in the order in which they are clinically recommended: simple ointment, oil-in-water emulsion and lubricating jelly. The "vanishing" stearate type of a base, in which penicillin seems to have the greatest power of corneal penetration, is not recommended because of its possible damage to the corneal epithelium. It may be used on the skin of the lids. For deep infections of the eye and retrobulbar tissues the parenteral route, although leaving much to be desired, is the only one available. Experimental studies demonstrated that a high concentration of penicillin can be achieved in the adnexa and tissues of the anterior segment, whereas the concentration within the posterior segment of the globe is, at the very best, minimal. As a corollary to this it might be expected that external ocular tissues, because of their accessibility, are readily cured by the use of this drug, whereas deep infections respond poorly or not at all. The correctness of this supposition is borne out by observations in 46 clinical cases reviewed by the author. He found that penicillin is effective in the clinical treatment of acute and chronic infections of the lids, conjunctiva and cornea produced by penicillin sensitive organisms. It was ineffective in 2 cases of exudative choroiditis and in 1 case of gonorrheal iridocyclitis.

Orthoptic Treatment of Phorias.—McCaslin stresses that ophthalmologists must give serious consideration to the phorias, since the patients in this group of "ocular imbalance" suffer great discomfort. The aviation industry has recognized the problem for several years; now industry in general has become conscious of its presence. The work of Tiffin and Kuhn proves that the accident increase is associated with high esophorias for distance and high exophorias for near work. Industry also is cognizant of the fact that it is far more economical to treat these employees than to train them for other types of work. These patients must first be subjected to a careful physical examination. Particular attention must be paid to the possible foci of infection, such as carious teeth, diseased tonsils and faulty habits of elimination; also the drinking habit. Following a thorough examination and refraction, a course of treatment is outlined to the orthoptist and the patient. Home treatment alone, even under the ophthalmologist's supervision, is not advocated. Few, if any, physicians have either the temperament or the time necessary to devote to the details of instruction and procedure that are required. The author has obtained excellent results working in conjunction with a well trained technician.

Intrathoracic Hodgkin's Disease.—According to Wolpaw and his associates, of 55 proved cases of Hodgkin's disease in which chest roentgenograms were made 35 showed intrathoracic involvement. The varied manifestations of intrathoracic Hodgkin's disease were correlated with the distribution of lymphoid tissue within the chest. Mediastinal, parenchymal, pleural, osseous and cardiac types were described and illustrated by 15 case reports. Just as roentgen rays have long proved of value in the treatment of Hodgkin's disease of peripheral involvement, radiation therapy has also been useful in the management of Hodgkin's lesions involving the thorax. The response of mediastinal tumors to small doses of radiation constitutes a differential diagnostic test between the lymphoblastoma group and lesions of different nature. As experience demonstrated retrogressions of mediastinal nodes following roentgen therapy, attempts were made to produce similar results on Hodgkin's disease involving the thorax. While retrogressions cannot be obtained with the same regularity as in the treatment of peripheral lymph node involvement, symptoms have been relieved and the duration of life has been prolonged. General medical therapy in conjunction with radiotherapy is essential if the best results are to be obtained. Twenty-three of the 35 cases were treated with radiation. Seventeen cases considered adequately irradiated showed favorable response of varying degrees. Three patients with adequate and 2 patients with inadequate dosage showed no favorable response, and in 1 case there was no record of the result of treatment. Because of the high incidence of involvement of the lymphatic chains of the mediastinum and abdomen found at necropsy, it has become routine in many clinics to irradiate these regions in all cases of Hodgkin's disease even though the lesions are not demonstrable by clinical or roentgenologic examinations.

Calcification of Choroid Plexus.—Wood says that calcification occurs in the choroid plexuses probably for the most part through a process of proliferation of cells of the pararachnoid followed by the formation of a dense collagenous and fibrous reticular meshwork in which calcium salts become deposited. Calcification occurring in the glomera of the choroid plexuses in the lateral ventricles assumes various forms and is

frequently asymmetrical. Wood describes 2 cases in which roentgenographically demonstrable choroid plexus calcification occurred in unusual positions and at very early ages (children of $2\frac{1}{2}$ and 3 years). One case exhibiting punctate calcification in the region of the fourth ventricle is reported. Two cases are described in which a displaced calcified choroid glomus was the only evidence on the plain skull roentgenograms of an expanding intracranial lesion. The author also reports an unusual case of upward and backward displacement of the glomus of a choroid plexus by an aneurysm of the basilar artery.

Parasternal Diaphragmatic Hernia.—Failure of fusion of the costal and lumbar portions of the diaphragm, Ritvo and Peterson say, results in a persistent pleuroperitoneal hiatus or foramen of Bochdalek. Lack of fusion of the sternal and costal portions forms the so-called foramen of Morgagni, with development of the parasternal diaphragmatic hernia. Comparatively few cases of the latter type of diaphragmatic hernia have been reported. Parasternal diaphragmatic hernias have frequently been misinterpreted as thoracic neoplasms. The authors have made the diagnosis in 6 cases, the majority of these having been first demonstrated by roentgenography of the chest and definitely confirmed by studies of the gastrointestinal tract. It is not universally agreed whether these hernias are congenital or acquired. There usually is a peritoneal covering, as proved both by necropsy and at operation, indicating that the peritoneum had been completely formed and had closed off the abdominal cavity from the pleural space before the hernia had developed. It is not possible to explain the occurrence of this lesion on the basis of faulty fusion or malformation of the various components of the diaphragm. The hernia can frequently be diagnosed by anteroposterior and lateral roentgenograms of the chest. The presence of gas filled loops of colon above the diaphragm in the right lower lung field is pathognomonic. The occurrence of a rounded mass in the anterior portion of the right lung field inferiorly and adjacent to the heart border requires that parasternal hernia be considered the diagnosis until proved otherwise. The transverse colon and omentum are usually found in the hernia, although other portions of the intestine may also be present. There is narrowing of the loops of colon at the points where they pass through the diaphragm. Barium enema studies are more satisfactory than the opaque meal examination in the demonstration of the lesion. The treatment is conservative and expectant in most instances.

Syphilis Transmitted from Congenitally Syphilitic Child to his Own Father. H. Ingraham, M. D. Kingston and A. Hesse.—p. 733.

Systemic Manifestations of Bismuth Toxicity.—According to Heyman bismuth therapy is relatively safe. Its usual reactions are mild, consisting chiefly of pigmentation of the gums and buccal surfaces or, less frequently, an ulcerative stomatitis. The use of bismuth is not without danger; deaths have been observed following its injection. Excluding the accidental intravenous deposition of the drug, most of these fatalities are caused by the toxic effects of the drug on the liver or kidney. Jaundice or nephritis is noted in these cases and there is frequently an associated stomatitis, colitis or hemorrhagic diathesis. Although such serious systemic reactions are uncommon, 4 cases with severe visceral manifestations of bismuth poisoning have been seen at Grady Hospital within the past few years. With the kidney serving as both the chief reservoir and route of excretion of the metal, this organ is most likely to be affected in cases of bismuth poisoning; and renal damage has been an almost constant finding in animal experiments. Presence of preexistent renal damage may increase the likelihood of developing toxic reactions. This association has been noted by many observers and seems to have occurred in the patients whose histories are reported, each of them having had hypertension with evidence of renal disease prior to bismuth therapy.

Two of the 4 described cases had a fatal outcome. The author directs attention to the occurrence of bismuth melanosis and cervicovaginitis in 2 cases and reviews the literature on this condition. He discusses the role of bismuth in the production of renal insufficiency and the similarity of the renal lesions to those produced by animal experimentation. The relation of previous renal damage to bismuth toxicity is emphasized, and caution is advised in the treatment of such patients with bismuth.

Renal Aspects in Differentiation of Terminal Glomerulonephritis and Malignant Hypertension.—Differential diagnosis in patients showing severe renal damage from chronic glomerulonephritis on the one hand and malignant hypertension on the other has always been difficult, because at this stage the two conditions have in common the clinical pattern of hypertension, loss of weight, anemia, so-called albuminuric retinitis, depressed renal function, azotemia, proteinuria and increased organized urinary sediment. Corcoran and Page selected for study two groups of patients who had in common the evidences of disease noted and who had not, at the time of first observation, progressed to uremia with its coma, acidosis and jactitation. They direct attention to diagnostic criteria derived from studies of renal function. They investigated the concentrating power of the kidneys, the urinary sediment, arterial pressure, hematocrit index and serum protein content. The studies were done on 10 patients from each group, selected because they presented the lowest levels of renal function observed in each series in the absence of the clinical syndrome of uremia. Terminal glomerulonephritis is distinguished by a low rate of glomerular filtration, of tubular secretory capacity and usually a higher rate of proteinuria than appears in malignant hypertension with renal failure. In spite of the lower level of renal excretory function in terminal glomerulonephritis, such patients survive more than four times as long as do patients with malignant hypertension in renal failure. The changes of renal function usually demonstrable in terminal nephritis are in accord with the structural changes in the kidneys in that they indicate glomerular and capillary lesions associated with great parenchymal destruction and fibrous replacement and suggest the frequent occurrence of large inequalities of function in the remaining nephrons. In malignant hypertension with renal failure intraglomerular hydrostatic pressure seems often increased and the flow of blood through the residue of intact tubular tissue is diminished, the latter presumably as the result of arteriolar constriction and (afferent) arteriolar sclerosis. In some of these patients, in spite of greatly increased arterial pressure and presumptive constriction of glomerular efferent arterioles, intraglomerular hydrostatic pressure seems not to be increased, or it is even low. This testifies to the severity of afferent arteriolar sclerosis or constriction in these patients. The conclusion is drawn that in these, as in patients with terminal glomerulonephritis, the implications of functional study agree with the structural changes caused by the disease. Evidence suggests that the hypoproteinemia of Bright's disease, whether it occurs during chronic glomerulonephritis or in malig-

nant hypertension with renal failure, apparently serves as a means of maintaining glomerular filtration when, in the absence of hypoproteinemia, the proportion of water filtered through the glomeruli would be grossly deficient or nil.

Cardiac Aspects in Differentiation of Terminal Glomerulonephritis and Malignant Hypertension.—In the comparison of the cardiac status of 10 patients with malignant hypertension in whom uremia was imminent with that of 10 patients with clinically similar chronic glomerulonephritis, Taylor and his associates found that 5 of the 10 patients with malignant hypertension developed clinical signs of heart failure in an average disease duration of five years, whereas only 1 patient with nephritis developed congestive failure in a group average of eleven years. In these two periods the same degree of cardiac enlargement developed in the two groups. In malignant hypertension the enlargement was primarily left ventricular and the aortas were long and tortuous. In nephritis the enlargement was globular and suggested dilatation. Electrocardiographic evidence of hypertensive heart disease is usual in malignant hypertension and rare in chronic nephritis. All of the patients with malignant hypertension had bizarre ballistocardiograms. This abnormality occurred in only 1 nephritic patient, in whom it was associated with heart failure. The blood pressure of malignant hypertension is usually higher, cardiac output is lower and peripheral resistance is greater, indicating more severe peripheral vasoconstriction or sclerosis or both as compared with chronic glomerulonephritis. The differential diagnosis between terminal malignant hypertension and terminal glomerulonephritis can be made by detailed study of the heart and circulation. Evidences of advanced heart disease are usual in malignant hypertension, whereas they are often indistinct or absent in nephritis.

Rupture of Heart in Myocardial Infarction.—Friedman and White attempted to determine the frequency and circumstances of rupture of the heart in a large general hospital. They found that cardiac rupture occurred in 10 cases, or 3.7 per cent, of a series of 270 instances of myocardial infarction found among nearly 3,000 necropsies at the Massachusetts General Hospital from 1933 through 1940. The 10 cases of cardiac rupture were found among the 105 patients with acute myocardial infarction (9.5 per cent) and none among the 165 cases of old infarction. The average age of the 10 patients was 65.7 years and the sex incidence was 7 males and 3 females. Death always ensued quite rapidly after the rupture, as evidenced by the state of the blood in the pericardial sac and the condition of the lacerated tissue. All 10 deaths occurred in less than two weeks after the clinical onset of acute myocardial infarction, most of them within a period of two to ten days after the illness began. In 8 of the 10 cases the descending branch of the left coronary artery and the anterior wall of the left ventricle were involved. In 1 case the circumflex branch of the left coronary was thrombosed and in the remaining case the circumflex branch of the right coronary.

Chronic Coccidioidomycosis.—Denenholz and Cheney show that, with military movement, soldiers trained in areas in which coccidioidomycosis is endemic may exhibit the manifestations of chronic coccidioidal infection in localities far removed

from the site in which the infection was originally acquired and in regions where this diagnosis is rarely considered. It is therefore highly important that medical officers be familiar with the chronic or residual manifestations of this disease. The authors have been particularly interested in the chronic phase of primary coccidioidomycosis and in disseminated coccidioidal infection, as the patients they observed have come under their care weeks to months after the illness first manifested itself. This report is based on observation of 14 patients proved to have clinical coccidioidomycosis and of 30 patients for whom the diagnosis was proposed but not confirmed. Of the 14 patients for whom the diagnosis was proved, 10 had primary benign and 4 had progressive disseminated coccidioidomycosis. Clinical study revealed the value and the limitations of the recognized diagnostic procedures, including investigation of the patient's history, physical examination, cutaneous and serologic tests with coccidioidin, culture and animal inoculation rate and roentgen examination. The case reports herein cited illustrate the common diagnostic errors and pitfalls that may be encountered in the clinical study of patients suspected of having coccidioidal infection. The authors found that medicinal treatment usually has little effect on this disease and that the primary consideration of therapy is rest in bed to aid focalization of the infection. Immobilization of the lung by a lead shot bag on the chest, which was used on some patients in this series, is a procedure not previously utilized and appeared to be of some benefit in helping to close the thin walled cavities caused by the coccidioidal infection. Acridine dyes (acriflavine hydrochloride and quinacrine hydrochloride) were tried but proved of no value. From a military standpoint, even though these patients with chronic coccidioidal infection may require long periods of hospitalization, they may often be returned to useful military service.

Intercapillary Glomerulosclerosis.—The association of intercapillary glomerulosclerosis with a distinct clinical syndrome was first pointed out by Kimmelstiel and Wilson in 1936. The characteristic symptom complex consisted of a history of diabetes mellitus, widespread edema of renal origin and pronounced albuminuria. Frequently hypertension and renal insufficiency were also present. The renal lesion was characterized by focal hyalinization of the intercapillary connective tissue and was named intercapillary glomerulosclerosis. Laipply and his associates aimed to determine the incidence of intercapillary glomerulosclerosis and to correlate its occurrence and development with distinctive clinical manifestations. For this purpose the clinical records, necropsy protocols and microscopic sections of 332 patients were examined. They arrived at the following conclusions: 1. At necropsy intercapillary glomerulosclerosis is a common lesion in diabetic persons and an uncommon one in nondiabetic persons. 2. It is more specific than hyalinization of the pancreatic islets as an indication of diabetes mellitus. 3. Because of its high incidence and clearcut character, it is at present the most reliable criterion available for the post-mortem diagnosis of diabetes mellitus. 4. There is no demonstrable relation between the degree of its development and the duration or degree of the diabetes. 5. It is not necessarily associated with hypertension, albuminuria, renal arterial and arteriolar sclerosis, uremia or the nephrotic syndrome. 6. The nephrotic syndrome is not a common accompaniment. It occurred in only 6.3 per cent of the diabetic patients with intercapillary glomerulosclerosis.

Decompression Sickness.—According to Bridge and his associates decompression sickness, or aetioembolism, is an acute disease with many manifestations produced by exposure to reduced atmospheric pressure. They analyze 167 man runs made by the 80 subjects doing 10 set ups every five minutes for ninety minutes in a decompression chamber at a simulated altitude of 38,000 feet. Eighty-five man runs (50.9 per cent) terminated prematurely in forced descent. The major cause was joint pain, of less importance were chokes, abdominal gas pain and hyperventilation. The remaining 95 per cent of descents were due to muscle pains, syncopal reactions and the like. Joint pains, with or without descent, occurred in 62.3 per cent of all man runs and were reported about equally for the two sides of the body. Pain in the knee (the joint most frequently affected) occurred in 53.9 per cent of all runs. The high incidence of pain in the anterior portion of the knee as compared with other regions of the knee was statistically significant. This seemed reasonable in view of the movements involved in the exercise. If knee pain recurred on successive flights, it was likely to appear in the same knee. Moderate and severe chokes were associated with joint pain in a significant number of instances. Postflight symptoms referable to joints affected at altitude occurred after more than 15 per cent of all runs. Nearly 26 per cent of those having joint pain at altitude had trouble with those joints during the postflight hours, and nearly half of these were joint swellings, probably representing synovial or bursal effusion. Postflight symptoms were reported for a few joints and muscles not affected at altitude.

Glycols for Air Sterilization.—Bigg and Jennings developed a practical means for the introduction of measured quantities of glycol into the atmosphere. They describe an apparatus of simple construction and operation which may be used for this purpose. The device was designed to introduce simultaneously, at predetermined rates, both water and glycol into the

air, thus eliminating the necessity of using a separate system for humidification. It is possible to accomplish this by boiling glycol-water solutions. The proportion of glycol and water vaporized in this manner will depend on their respective concentrations in the liquid phase, and the rate of introduction into the air will be determined by the heat input (rate of boiling). The practicality of this method has been fully demonstrated in field trials. The method eliminates fire hazards, regulates desired humidities, may be built at a nominal cost and is flexible in its application and simple in operation. Glycol vapor introduced in this manner is equal in bactericidal activity to that produced by other methods.

Variability of Heart Rate and Blood Pressure in Students.—Salit and Tuttle point out that, if cardiovascular measures are to be used to identify persons in good and poor physical condition or to measure progress during the course of a training program, these measures must have reliability and discriminatory power. They report investigations to determine which of several commonly used cardiovascular measures are most reliable. The studies were made on college men and women and on high school boys. The authors found that the pulse after a standard exercise is a more reliable measure than the resting pulse, but the resting systolic blood pressure is a more reliable measure than the systolic pressure after exercise. Even when conditions are carefully controlled, an individual's heart rate and blood pressure are so variable from day to day that a number of determinations must be made if his general status is to be established. Cardiovascular tests in general have little discriminatory power because the differences in scores among individuals are small in relation to individual variability. Individuals can more clearly be distinguished from one another on the basis of postexercise pulse rates than on the basis of resting heart rate or the increase due to moderate exercise. The same is true of postexercise systolic and diastolic blood pressures. The relative efficiency of heart rate scores in distinguishing individuals from one another has been demonstrated in terms of the percentage of significant differences among individuals in a group. Whereas only 8 per cent of the differences in the resting pulse for the 20 men in this experiment are significant at the 1 per cent level of confidence, 41 per cent of the differences in pulse one-half minute after exercise are significant at this level. The corresponding figures for the women are 25 per cent and 32 per cent. At the 5 per cent level of confidence, 62 per cent of the differences in pulse after exercise are significant among the men; among the women only 53 per cent of the differences are significant at this level of confidence.

Oscillometer and Thermocouple in Diagnosis of Peripheral Vascular Disease.—Moscs and Ferderber recorded the evidence obtained by various diagnostic procedures and correlated this evidence with the circulation in the extremities examined. Observations were made on 102 persons. This group included 48 normal subjects, 8 asymptomatic, 6 with thromboangitis obliterans and 28 with arteriosclerosis. Observations as to history, symptoms, physical signs, oscillometric readings, skin temperatures, blood flow and vibratory sensation were noted and the results tabulated. While in arteriosclerosis of the lower extremity symptoms referable to the calf were most common, pain was noted almost as frequently in the ankle, arch, dorsum or toes. Numbness, tingling, burning, aching and rest pain were symptoms noted almost as frequently as inter-

mittent claudication in arteriosclerotic vascular diseases. A feeling of local fatigue was often the first sign of vascular disease. Arteriosclerotic rest pain was often relieved by moderate exercise. The pain of thromboangiitis obliterans was not relieved by exercise. Normal distribution of the hair over the lower extremity was noted in only 25 per cent of the patients with vascular disease. Rubor, cyanosis or pallor of an extremity may be present in the absence of arterial vascular disease. The absence of the dorsalis pedis or posterior tibial pulsation did not exclude vascular disease. The oscillometric readings were not necessarily found to be decreased in arteriosclerotic peripheral vascular disease; normal individuals with heavy musculature may have diminished oscillometric readings. Normal skin temperatures may obtain in individuals with vascular disease. Estimation of the blood flow by Stewart's calorimetric method indicated that the blood flow in patients with vascular disease averaged about two-thirds that in normal subjects. Estimation of the vibratory sense by the method of Barach yields confirmatory evidence of deficient circulation but is of little early diagnostic value. The arteriovenous anastomoses are suggested as one mechanism partially explaining the variations in skin temperature that occur in normal individuals and those with peripheral vascular disease.

Eosinophilic Granuloma of Skull.—According to Campbell and Alexander, eosinophilic granuloma of bone is a relatively rare condition affecting chiefly children and young adults, usually males. The lesion is benign, may be solitary or multiple and in more than half the recorded cases has affected the cranial vault. Although the x-ray film of this lesion is suggestive, a diagnosis cannot be made without biopsy and microscopic study. Eosinophilic granuloma usually starts as a well localized lesion in the medullary cavity, tending to erode, expand and perforate the cortex. In the calvarium it may erode either inward or outward, and several cases have been recorded in which a considerable area of the dura underlying the bone lesion has been directly involved. There have not been cases in which the brain has been involved, nor does the tumor apparently have any tendency to erode into blood vessels. Grossly the tumor appears soft, is sometimes quite hemorrhagic and gives the impression of being malignant. Microscopically the picture varies considerably from case to case, apparently depending on the length of time the lesion has been present. As a rule the

lesion is characterized by the presence of compact aggregates of large phagocytic cells, called histiocytes by some, with conspicuous collections of eosinophils. The eosinophils may be such a prominent feature as to stain the entire field red to first inspection in a hematoxylin and eosin stained slide. There is an intimate pathologic relationship of this lesion to Schüller-Christian disease and Letterer-Siwe disease. The prognosis of eosinophilic granuloma is almost universally favorable. Cases of spontaneous healing have been recorded. Other patients have been apparently cured by surgical extirpation, curettage and x-ray therapy. The authors observed eosinophilic granuloma in the left frontal bone of a soldier stationed in the South Pacific theater. The tumor was extirpated and the wound healed by primary intention. Later, at a hospital in the United States, the skull defect was covered with a tantalum plate.

Post-Traumatic Headache.—Brenner and his associates report observations on 200 consecutive hospitalized patients with head injury between the ages 15 and 55 years who were followed from the time of injury for a period of six or more months. One hundred and thirty-eight patients complained of post-traumatic headaches, 63 patients of headaches lasting longer than two months and 59 patients of headaches that did not persist beyond the hospital stay. In 11 patients the headaches began after discharge from the hospital. Post-traumatic headaches are regularly intermittent. They may be precipitated by postural changes, effort, fatigue or emotional upsets, or they may appear without relation to any such factors. They are characteristically variable from patient to patient with respect to severity, character of pain and localization. Headaches lasting for longer than two months were associated with dizziness and nervous symptoms (fears, anxiety, fatigue, irritability and/or inability to concentrate). The incidence of such prolonged headaches was high among patients with nervous or neurotic symptoms prior to injury, with complicating environmental factors (including compensation), with symptoms of immediate emotional reaction to the injury and with scalp lacerations; it was low among recreational accidents and among patients with very mild head injuries. These relationships suggest the importance of both psychologic and physical factors. Even in headache localized to the region of known damage to scalp or skull, psychologic factors had high correlation. A striking liability of headache localized to the site of previous scalp injury to provocation by posture or physical effort provides evidence that such provocation in more diffuse types of headache indicates underlying structural damage. A liability of provocation by histamine, particularly when the headache has been unilateral, suggests that intracranial localized vascular or perivascular change may occur. Neither changes in the spinal fluid, in the electroencephalogram, in the reflexes, in the degree or extent of scalp or cranial injury nor in the extent of disorder of consciousness immediately after the injury give adequate prognosis of subsequent liability to headache. Headache was, however, significantly less common in those who had no initial disorder of consciousness.

Intravenous Feeding of Complete Diet in Child.—Helfrick and Abelson present the history of a 5 month old infant with Hirschsprung's disease, a digestive upset and upper respiratory disease. The infant developed the extreme picture of marasmus, which gave every indication of an impending fatal termination. The baby was given a complete intravenous feeding for five days with fats, carbohydrate and amino acids in proportions and quantities recommended in a normal infant's

diet. There was a prompt dramatic improvement in the nutrition, permitting eventual successful treatment of the Hirschsprung's disease with neostigmine. The authors believe that this is the first case on record of complete feeding by vein alone for a significant period. The success in this child suggests strongly that total feedings by vein can be a practical and life saving procedure, especially applicable to children who are marasmic or are unable to handle an adequate diet by mouth, or in whom it is desirable to withhold oral feedings for therapeutic purposes.

The Physician and Control of Gonorrhea in the Armed Forces. E. M. Cohart and O. F. Hedley.—p. 210
Doctor's Laboratory. A. J. Fuller.—p. 211.

Penicillin for Sulfonamide Resistant Gonorrhea.—Wigh and Geer present a report of 191 consecutive cases of sulfonamide resistant gonorrhea treated at a station hospital. A patient was considered sulfonamide resistant if he had not responded to the following minimal dosage schedules: one duty course of sulfathiazole or sulfadiazine consisting of 1 Gm. of the drug four times daily for five days (20 Gm.) plus one hospital course of either drug, beginning with 4 Gm followed by 1 Gm every four hours, day and night, for five days (33 Gm.). The average duration of disease was 1.7 months. The average amount of sulfonamides a patient had received was 88 Gm. Injections of 10,000 units of penicillin in 3 cc. of water were administered intramuscularly into the gluteal region. Two schedules of treatment were used. All patients initially received a total of 50,000 Oxford units. This was administered in five doses at three hour intervals. The second schedule was used only for those patients who were clinical failures after the first schedule. It consisted in the injection of a total of 100,000 units in ten individual hourly doses. Patients not cured by these two schedules were given fever therapy. There were no systemic reactions to the penicillin. Eighty-nine per cent of the 191 patients were cured with 50,000 units of penicillin. Retreatment of the 21 failures with an additional 100,000 units resulted in cures in 98.95 per cent of the entire group. Two patients did not respond to a total of 150,000 units. A large proportion of those requiring an additional 100,000 units had complicated gonorrhea. Although 50,000 units of penicillin will cure most patients with gonorrheal manifestations other than urethritis, it is not possible to predict which patients will need larger dosages than 50,000 units. Proportionately more Negro than white patients are cured with 50,000 units of penicillin.

Primary Atypical Pneumonia of Unknown Etiology.—Gundersen says that from January 1942 to February 1944 inclusive 162 patients with a final diagnosis of primary atypical pneumonia were seen at his hospital. In all of them there was a confirmation of the diagnosis of pneumonia by x-ray examination. In this analysis 122 cases, including 3 fatal cases, 2 of which came to necropsy, are used. Cough, headache, malaise and sore throat were the most frequent symptoms in the order named. Shaking chills were relatively infrequent. Cough was often slow in development. In most cases it was explosive, hacking and distressing; in the average case it gradually became productive of small amounts of mucopurulent sputum. Of great importance for the differential diagnosis was the complete absence of typical pleuritic pain and of "prune juice" or rusty sputum. The term "atypical pneumonia" is particularly appropriate in relation to the question of physical findings, which were few. The sputum was examined in every case. Eighty-two cases showed many organisms in the cultures, with no one of them predominating. Typable pneumococci were found in small numbers in only 4 of 77 cases examined for this purpose. Sulfonamides were given as a therapeutic and diagnostic test in 63 cases without perceptible beneficial effect. The diagnosis of pneumonia was confirmed by x-ray examination in all cases. Patchy areas of infiltration with indistinct borders were considered most typical, but several cases of distinctly lobar consolidation were seen. Accentuation of the lung markings, giving a streaked appearance of the involved area, was more pronounced than it is in most cases of bacterial pneumonia. A few of the x-ray films taken separately and without regard for follow-up study could easily have been interpreted as indicating pulmonary tuberculosis. In addition to providing bed rest, good nursing care and adequate intake of fluids and salt to combat unusual loss from sweating, the treatment was directed toward relief of the most annoying symptoms. Inhalations of steam, expectorants containing iodine and codeine afforded the best relief from cough, especially in the early stages. Salicylates, with or without codeine, gave fair relief from headaches. Hot gargles or irrigations of saline or weak perborate solutions were frequently used for sore throats. In the first fatal case the poor response to treatment was possibly due to the blood

changes resulting from infectious mononucleosis. The second fatal case gave a history of pneumonia eight months previously. The third patient who died had suffered from asthma for a long time and was an alcohol addict.

Positive Transference in Schizophrenia Case D. A. Barbara—p. 674.

Divergent Outcome of Schizophrenia in Identical Twins.—Arieti observed a pair of schizophrenic monozygotic twins. The symptoms presented by the patients were fundamentally similar, but whereas 1 of them made a spontaneous recovery, the condition of the other was practically unchanged after more than two years. The patient recovered who was the more athletic and less asthenic, whose prepsychotic personality was definitely more extroverted, who had always shown better ability to cope with the problems of life and whose symptoms were somewhat atypical because of the presence of many "psychoneurotic" symptoms.

Psychosomatic Aspects of Allergy.—Karnosh thinks that neurologists or psychiatrists cannot ignore the emotional, mental and neural phenomena which are interlocked with the allergic reaction in human tissues. That the brain is capable of a direct and profound reaction to protein hypersensitivity has been clearly demonstrated by many investigations made on laboratory animals. The contentions of many clinicians that such conditions as migraine, Ménière's disease, infantile convulsions, transient paralysis and psychosis are expressions of allergy within the cranial cavity are not entirely without rational support. The author is chiefly interested in the question of the influence of the mind on the allergic lesion and, conversely, the influence of the allergy on the mind of the patient. He cites a schizophrenic patient in whom there existed a close parallelism between skin allergy and mental disease. The skin is a powerful organ of emotional expression—perhaps next to the voice and the facial muscles, it is the best expression of human feeling that can be freely observed. There is the blush phenomenon in self-consciousness, the paroxysmal sweating in anxiety states and the pallor, lemon tint in melancholia. Itching, like pain, may appear at the site of psychic fixation. The same sym-

thetic nervous excitations in the skin, such as vasomotor irritability, increased sweating and pilomotor excitement, are expressions of the emotions as well as of allergy. The author shows that, the more one studies allergic patients who suffer from "nervousness" or take an "erratic slant" at themselves and their troubles, the more one recognizes that these nervous reactions are not greatly different from those which follow in the wake of any chronic, irksome, disabling and irritating affliction. Even though one cannot establish a causative relationship between allergy and nervous and mental disease, it can be said that almost always, to some degree, the two afflictions are concomitant in the same person. No allergic patient can be adequately evaluated without considering the personality structure in which the disease is implanted.

Smith-Petersen Nail and Fibular Bone-Graft in Fractures of Neck of Femur.—Ossman and Brooke state that early manipulative reduction followed by internal fixation with metal nails, screws or pins is now generally accepted as the best method of treating fractures of the neck of the femur. The results are so gratifying, as compared with the older methods of sand bags, weight traction or even the Whitman abduction casts, that there should seldom be an excuse for using the older methods. From a study of older and more recent literature the authors estimate that the mortality rate has been reduced from about 25 per cent with the older methods to about 10 per cent with the newer methods. The incidence of nonunions has been reduced from approximately 75 per cent to 25 per cent. When early reduction and fixation are not obtained, disaster may be avoided by combining the Smith-Petersen nail fixation with the additional insertion of a fibular bone-graft across the fracture paralleling the nail. Thus combined extra-articular osteosynthesis was first described and used with good results by King of Australia in 1939. The authors report the histories of 2 patients whom they treated in this manner. This treatment is useful in some cases of nonunion following fracture of the neck of the femur.

Orchiectomy in Carcinoma of Breast.—Treves and his associates say that the encouraging regressions of the skeletal metastases from mammary carcinoma following castration in women still menstruating suggested the possibility that orchiectomy

tony might retard or even cause regression of mammary cancer in the male. The latter experiment was begun more than two years ago at the Memorial Hospital in New York. The consent for orchiectomy, even in the elderly man with advanced breast cancer, was most difficult to obtain. Even an elderly man with intense pain from osseous metastases was unwilling to undergo castration. It seems to be more difficult to obtain permission for castration in males suffering from mammary cancer than in malignant disease of the prostate. The authors present histories of 6 patients who underwent castration because of carcinoma of the breast. The first patient, a man aged 72, experienced a satisfactory and dramatic regression of a primary carcinoma of the male breast which had metastasized to bone. The breast cancer was replaced by a cicatrix, the metastatic nodes regressed. The secondary deposits, as demonstrated in repeated x-ray films, showed reparative change. The repair in the ribs, shoulder girdle and spine were striking. The second patient, aged 75, who had undergone mastectomy, at first refused an orchiectomy. Lesion of the scalp and skeletal pain induced him to submit to orchiectomy, but he died on the third post-operative day. His death was probably hastened by his poor physical condition, the result of associated disease, probably hepatic cirrhosis. The third patient, a man aged 65, obtained a very satisfactory result from orchiectomy. He has been relieved of his pain and has maintained his good physical condition. The phosphatase level has returned to normal, and the x-ray studies show evidence of bone regeneration. The fourth patient has remained free of local or distant disease following the local excision of a carcinoma of the left breast. The only adjuvant therapy was the orchiectomy, which at the time had not been planned as a therapeutic measure but for the relief of a bilateral hydrocele. The result is most satisfactory one year after treatment. In the fifth patient, who was only 39, castration in no way altered the clinical course. The failure to respond may have been due to the patient's comparatively early age. In the sixth patient there has been an arrest in the growth of the primary lesion with some regression in the tumor, healing in the skin and disappearance of the cutaneous metastases.

Papillary Cystadenoma Lymphomatosum of Parotid Salivary Gland.—Martin and Ehrlich undertook to determine the clinical behavior of papillary cystadenoma lymphomatosum of the parotid salivary gland. Their report is based on 22 cases culled from the records of 359 parotid tumors, all observed in the head and neck service of the Memorial Hospital, New York, from 1932 to 1944 inclusive. The authors apply the term "papillary cystadenoma lymphomatosum" to an essentially benign cystic tumor occurring either in the parotid salivary gland or attached to it. Its microscopic appearance is characterized by specific epithelial structures supported by a lymphoid stroma. Other terms that have been employed to designate this neoplasm are adenolymphoma, branchiogenic adenoma, epitheliolymphoid cyst, branchioma, cylindrocellular branchiogenic adenoma, orbital inclusion adenoma and onkocytoma. In 1910 Albrecht and Arzt first established this tumor as a distinct morphologic entity. There have since been reported 66 cases exclusive of the present series. In 1929 Warthin discussed the cases already in the literature and added 2 of his own. Since then the growth has often been referred to as Warthin's tumor, an eponym hardly justified from the standpoint of precedence. The ages of the patients whose cases are reviewed varied between 30 and 73 years. There were 20 men and 2 women. The women patients were rather young, 36 and 37 respectively. Cystadenoma lymphomatosum is an encapsulated tumor. The capsule is thin, strong and glistening and is traversed by fine blood vessels. The specimens varied from 1.5 to 5.5 cm. in greatest diameter and were ovoid and globular. The histogenesis of the tumor has not been definitely established. There is a reasonable anatomic basis to support the theory of its origin from heterotopic salivary gland rests situated in lymph nodes adjacent to or within the parotid gland. The neoplasm is a distinct morphologic entity, but it cannot be distinguished clinically from the relatively common mixed parotid tumor. Cystadenoma lymphomatosum recurs promptly if surgical excision is not complete. All tumors in this series were anatomically and clinically benign. There are no satisfactory data to indicate whether the tumors are radiosensitive or radiocurable.

Influenza Virus as Laboratory Contaminant.—Andrews and his associates have described the recovery during the recent influenza A outbreak of two virus strains which proved serologically identical with the stock laboratory strain PR8 and, like it, of very high mouse virulence. These features led the authors to suspect that the strains might be "laboratory contaminants." They have been led by these occurrences to collect other instances in which laboratory contamination is suspected. Fourteen incidents are described as occurring in ten different laboratories. The fourteen "incidents" described may have diverse explanations. Some of them may be explained by inadequate sterilization of instruments or glassware. Others may have been genuine isolations of a virus like W. S.; it is unlikely that that virus is unique. Its repeated appearance under the conditions described seems highly suggestive. The series as a whole convinces the authors that influenza virus can turn up as a laboratory contaminant under conditions not yet understood. The appearance of such a contaminant may lead to temporary confusion. The authors emphasize that workers on influenza should keep the possibility of contamination constantly in mind.

Hemorrhagic Encephalitis and Intensive Mapharsen Treatment.—According to Lydon at one center 5 out of 53 patients with early syphilis, who were treated by a short term intensive course of mapharsen, developed hemorrhagic encephalitis or, as he prefers to term it, arsenical encephalopathy. The intensive mapharsen treatment was administered only to patients with early syphilis who had been given the following tests: (1) a complete blood count, including differential leukocyte count and total number of platelets; (2) the van den Bergh test and icterus index; (3) urine analysis for abnormal constituents such as albumin, sugar and bile. Urinary examinations were carried out daily and the van den Bergh and icterus index tests were performed on alternate days. At the end of the course a complete blood count was again made. Five injections, of 0.03 Gm. of mapharsen in 5 cc. of doubly distilled sterile water were given intravenously daily at two hourly intervals for five days. The total dose of mapharsen given was 750 mm. Glucose in large quantities was administered daily and, in addition, each patient received 200 mm. per day of ascorbic acid. After 3 cases of arsenical encephalopathy had developed, modifications were introduced, which included administration of vitamin B₁; spinal puncture and examination of the spinal fluid on the fourth day; prolongation of the treatment to six days, and blood sugar estimations on the first and fourth days. The author describes the histories of the 5 patients who developed hemorrhagic encephalitis. The reason he prefers the term arsenical encephalopathy is that neither hemorrhage nor inflammation is necessarily a pathologic feature. He defines the con-

dition as an acute cerebral complication which occurs during arsenical therapy and is characterized clinically in its early stages by changes in the mental sphere which are of two distinct types, (a) lethargic and (b) apprehensive. The onset is accompanied by changes in the cerebrospinal fluid, namely increased protein, positive Pandy test without increase in cellular elements and no change in sugar or chloride contents. The early recognition of these mental changes is of importance both for cessation of the arsenical drug and for institution of treatment. A peculiar oral fetor, widely dilated but normally reacting pupils and obstinate constipation are often observed. At a later stage various signs make their appearance, such as emotional instability and perseveration. Convulsions may occur, usually within the first few days; they are of serious import and probably indicate hemorrhage into the brain substance. Alcoholism and vitamin B₁ deficiency seem to be predisposing factors. Vitamin B₁ is suggested as both a prophylactic and a therapeutic agent; calcium gluconate is also used as an adjunct. Venesection, repeated lumbar puncture, and puncture and epinephrine seem to be of value. On the basis of the author's own experience and from a perusal of the available literature on intensive mapharsen therapy encephalopathy appears to occur many times more often under this method than under the various long term schemes of antisyphilitic treatment. He thinks that it is necessary to carry out extensive research into the causation and treatment of encephalopathy before intensive mapharsen treatment can be applied generally.

Plasma Volume in Traumatic Shock.—Crooke and his associates show that the estimation of plasma volume in patients with traumatic shock has been beset with difficulties; the estimation of Evans's blue in plasma is unreliable in nonfasting subjects and also in subjects who have received morphine or scopolamine. Repeated measurements of hemoglobin by the pyridine-hemochromogen method of Rimington and of the hematocrit revealed that the two values run parallel. The determination of hemoglobin is more accurate than that of the hematocrit. Total blood volume cannot therefore be determined, but it gives little more information than plasma volume when the hemoglobin value is also known. Reduction of plasma volume is accepted as being characteristic of traumatic shock, the amount of the fall being proportional to the severity of the shock. In general this has been confirmed in the present series of cases, but the reduction is greatest when examined early, as shown by the first 2 patients, both of whom died of their injuries. In case 1 the plasma volume had fallen from the normal level of between 4.5 and 5.5 per cent of body weight to about 2.1 per cent in less than two hours. This patient died two hours later. In case 2 plasma volume was about 3.3 per cent of body weight seven and one-half hours after the patient sustained a ruptured kidney and spleen. She died sixteen hours after the injury. In less severe cases the reduction of plasma volume may be slight, especially if not examined until some hours after the injury. Hemoglobin concentration falls following traumatic shock, but the fall is minimal immediately after the injury and may not become severe until several hours later. The reduction of plasma volume in all the cases which the authors examined could be explained by hemorrhage alone, but many workers have claimed that shock is a toxic condition associated with hemoconcentration. Hemoconcentration as judged by increased concentration of hemoglobin or a hematocrit value above the normal has not been observed in the cases in this series except when associated with burns or with the crush syndrome. Hemoconcentration in these cases is due to loss of serum into the damaged tissues without a corresponding loss of corpuscles.

The conception that hemoconcentration occurs in traumatic shock in man is probably due to the cyanosed, viscid character of the blood in severe cases. The authors have found, however, that in contrast to this increased viscosity of whole blood the viscosity of plasma is below normal. The increased viscosity of the blood with a decreased clotting time and a normal hemoglobin suggests a state of incipient clotting. The fibrinogen content of the plasma was, however, found to be normal by electrophoresis. The increased viscosity of the whole blood may therefore be due to an abnormal state of dispersion and of the alpha component, since it is known that both alpha and beta components readily form gels under certain abnormal conditions. This gel would be removed in the centrifugal separation of cells and plasma, and such plasma would have a decreased viscosity, a deficiency in alpha component and a normal fibrinogen content.

Laboratory Test for Diagnosis of Smallpox.—Observations on over 100 patients with smallpox studied in the Middle East has convinced van Rooyen and Illingworth that a diagnosis of variola on the first and second day of the rash is often extremely difficult and that the differentiation of mild smallpox from varicella may be impossible throughout the course. They were able to confirm Paschen's observations that the elementary bodies of variola are larger than those of varicella. They utilized this observation as the basis of a laboratory test for the identification of smallpox. Paschen uses Löffler's flagellar mordant and carbol fuchsin stain. The authors select 6 early lesions, preferably fresh vesicles containing clear fluid, and these are opened with forceps. If the lesion is a vesicle, the fluid is first absorbed with cotton. The base of the exposed cavity is then firmly scraped and the material obtained is rubbed with a rotary motion on the surface of a glass slide. Three such smears can be made on each slide. Best results are obtained by scraping the earliest papular and vesicular lesions; pustules should be avoided, as these often contain artefacts. The authors made skin scrapings in 80 cases of smallpox ranging in severity from mild to fatal hemorrhagic variola. These were subjected to the film test for elementary bodies. The laboratory and clinical findings corresponded in 77 cases. A negative result was returned in 3 cases of smallpox. Variola elementary bodies were demonstrated with ease in the papular and vesicular stages of the illness, but after the onset of pustulation they tended to disappear. In 32 cases of early smallpox the laboratory answer was positive on the first day of the rash, when it was very sparse and the clinical diagnosis was difficult or impossible to establish. In no instance did a positive laboratory verdict disagree with the final clinical diagnosis of the case. Control skin scrapings from 64 clinical cases of varicella occurring in Egypt, together with a further 16 cases of chickenpox contracted in England, have been studied under identical conditions and compared with similar material from 80 cases of variola in Egypt. The film test is not applicable to the diagnosis of chickenpox because the elementary bodies of varicella are too small, are too scanty and show feeble affinity for Paschen's stain.

Air Embolism as Complication of Vaginal Douching in Pregnancy.—Forbes reports the history of a woman aged 34 who had had three previous pregnancies and who complained of poor health on June 30, 1943 but attributed her symptoms to the onset of menstruation. She usually had dysmenorrhea severe enough to require two or three days in bed. She began to menstruate on July 1. Next day she collapsed on her way to bed and died a short time later. At the time of the necropsy there was nothing to suggest the cause of death. When the abdomen was opened a gravid uterus was found. Opening the uterus revealed the placenta low on the right lateral wall and its lower edge detached to a depth of 1 inch. The membranes were separated to a depth of 2½ inches. The uterus contained a fetus of three months' gestation. The lungs were very edematous. The pericardium appeared normal. The right side of the heart was dilated, and the auricle and ventricle were found to be filled with frothy blood. The pulmonary artery contained identical material. The possibility of air embolism was not thought of before the necropsy, and consequently the special technic usually followed in such cases was not adopted. However, the findings indicate conclusively that this was the cause of death. The obvious suspicion was that this case was one of criminal abor-

tion. Further inquiries revealed that the woman had not missed a menstrual period, and on June 3, 4 and 5 she was medically attended for dysmenorrhea. Neither her husband, her friends nor her doctor knew that she was pregnant. There is definite evidence also that during one of her previous pregnancies she continued to menstruate for three months after the pregnancy began. There seems, therefore, to be some doubt whether she realized that she was pregnant. She was accustomed to using a Higginson's enema syringe for vaginal douching and, though no definite evidence on this point was forthcoming, it seems likely that she douched immediately before retiring. The author points out that there are 3 cases on record in which vaginal insufflation during pregnancy had resulted in death from air embolism. So far as can be ascertained there is no previous report of an instance in which simple vaginal douching led to air embolism from detachment of the placenta.

*Treatment of Chronic Suppurative Otitis Media by Local Application of Penicillin and Other Drugs. E. G. Collins and K. E. A. Hughes. —p. 81.

Use of Amnioplastin in Surgery of Ear. M. Sugar. —p. 96.

Autoanesthetic Apparatus Suitable for Ear, Nose and Throat Work. T. B. Jobson. —p. 101.

Penicillin and Other Drugs in Chronic Suppurative Otitis Media.—Collins and his associates carried out studies to determine whether the local application of penicillin would prove a satisfactory remedy for chronic suppurative otitis media. Twenty-three patients were admitted to the hospital for this investigation, but only 9 of these were treated with penicillin; the remainder were treated by other methods. In 4 of the 9 patients treated with penicillin a dry and sterile ear was obtained, while in 12 of the remaining 14 a similar result was achieved. The percentage of successful cases was influenced by the bacteriology of the aural discharge. The response divided the patients into two groups according to the sensitivity of the organisms to penicillin. The conclusion is drawn that the local use of penicillin will be limited in this disease owing to the types of organisms present and the difficulties of application. Boric acid in alcohol was employed locally in 16 of the cases and appeared to have a good bacteriologic and clinical effect in about half of those patients from whose aural discharge diphtheroid or "coliform" bacilli were cultured. The proteus bacillus was affected only if the discharge was slight, and the authors suggest that when the proteus is a saprophyte this solution will be effective but that when the proteus is a pathogen it will not prove successful. The staphylococcus and streptococcus did not appear to be influenced by this solution. Boric iodine powder was employed in 9 cases. The powder gave results similar to the boric acid in alcohol, though it appeared to be more effective against the "coliform" bacillus. Its action against the proteus was limited. Sulfanilamide powder, succinylsulfathiazole powder, sulfacetamide in solution and sulfathiazole in a cream suspension were tried locally. None of the sulfonamides used locally appeared to influence the proteus cases. Staphylococci were unaffected bacteriologically, though clinically there was less discharge and the general appearance improved. Sulfathiazole was given by mouth to 10 patients. In 4 patients with "coliform" organisms in their discharge, who had improved slowly with boric acid in alcohol, oral administration of sulfathiazole rendered the ears sterile and practically dry. The same favorable effects were obtained in 2 of 3 patients with proteus infection. Two of 3 patients with diphtheroid infection seemed benefited, but not the third. A short course with large doses of sulfathiazole will probably give better results than smaller doses over a long period and will be less dangerous. The authors gained the impression that of all the bacilli found in the aural discharge the staphylococcus and the proteus are the main enemies, and if these two organisms are in combination they appear to be very intractable to treatment. The bacteriology also suggests that the external route of infection may be more important than we imagine and that more attention should be given to the prevention of reinfection of a dry open perforation by dirty water from washing or the screwing of dirty towels into the ears.

Optic Neuritis in Poliomyelitis.—Bergman and his associates report the case of a girl aged 9 who presented the clinical picture of acute meningoencephalitis with respiratory paresis, paresis of the right arm and right leg, paresis of central type of the right facial nerve, paresis of the palate and slight stiffness of the neck. The patient was placed in the respirator for twenty-two hours, and all the signs of paresis disappeared. Double optic neuritis was observed one month later. A diagnosis of poliomyelitis was made because at the time of the patient's admission to the hospital a poliomyelitis epidemic was in progress, many cases of which presented the same clinical picture as in the case reported. The diagnosis was clarified by an experimental investigation: Intraperitoneal and cerebral injections of etherized stool suspensions (50 cc. and 0.5 cc. respectively) from a fecal specimen taken the day following the patient's admission to the hospital were given to a *Macacus rhesus* monkey. Twenty-seven days later the monkey was killed. While alive it did not present any symptoms of paralysis. Hyperemia of the axillary, inguinal and mesenteric lymph nodes was demonstrated at necropsy. Perivascular mononuclear meningitis was revealed on microscopic examination of the central nervous system. Massive perivascular cell infiltration characteristic of experimental poliomyelitis was found beneath the cortex of the brain, in the walls of the lateral ventricles and in the area adjacent to the aqueduct of Sylvius. There were no such changes in the gray substance of the spinal cord, but a mononuclear cellular focus was found in the white substance of the upper part of the dorsal spinal cord. A few typical neuronophages were observed in the ventral wall of the aqueduct. Three weeks later intraperitoneal and cerebral injections of an emulsion of the brain substance of the animal were given to a second *Macacus rhesus* monkey. The examination of this monkey was negative while the animal was alive, but hyperemia and enlargement of the inguinal and axillary lymph nodes was demonstrated likewise at necropsy. Occasional perivascular infiltrations were found in the walls of the lateral ventricles and the floor of the fourth ventricle. Perivascular meningitis of the thoracic spinal cord, characteristic of poliomyelitis, was revealed. On the basis of these findings the optic neuritis was considered to be caused by the same infection.

Noncardiac Familial Cyanosis.—In 1941 Thysell observed 4 cases of cyanosis at the Gothenburg Children's Hospital involving a father and his 3 children. The skin of the mother, a half-sister to the 3 children (the mother's child in a former marriage) and the remaining relations were of normal color. All 4 had been blue since birth. They had developed normally and had no subjective difficulties such as dyspnea, palpitations or fatigability. The cyanosis appeared somewhat increased on physical exertion. Neither cardiac insufficiency nor any other cardiac alteration could be demonstrated. Oxygenation of the venous blood was normal. There was no polyglobulism. Spectroscopy of the blood gave normal results. Lundsgaard's contention is that the cause of cyanosis is to be sought in the reduced hemoglobin content of the capillary blood. Recent capillary microscopic studies of severe cases of cyanosis demonstrated that the color of the skin depends fundamentally on the degree of fulness of the end capillaries. Capillary microscopic examination of the vessels in the end phalanges of the fingers of the author's 4 patients showed highly abnormal vascular structure with formation of nodules and of aneurysm, spiral contortions and formation of bridges in a dilated and blood distended subcapillary capillary network. The author wonders whether this familial cyanosis can be due to an independent, stationary disorder, not hitherto described in the literature, of the subcapillary plexus (the substratum of the cyanosis) or in a congenital malformation of it. Necropsy might reveal a congenital defect complementing the capillary disorder.

Book Notices

An Introduction to Public Health. By Harry S. Mustard, B.S., M.D., LL.D., Director, and Professor of Public Health Practice, Delamar Institute of Public Health, College of Physicians and Surgeons, Columbia University, New York. Second edition. Cloth. Price, \$3.25. Pp. 283. New York: Macmillan Company, 1944.

The author, an experienced public health administrator, has condensed into a brief space a complete summary of public health procedures. He begins with a discussion of backgrounds and associations of hygiene and public health, including a swift historical review. He then discusses vital statistics and the importance of record keeping in public health procedure. This is followed by an explanation of the organization and administration of public health units of various kinds, including suggestions as to appropriate salaries for various positions. Brief mention is made of the voluntary health association. Next follows a chapter on the handling of the acute communicable diseases. Tuberculosis is given extensive consideration in a separate chapter, as are the venereal diseases. Then follows material on sanitation and, in the order named, industrial hygiene, individual hygiene, child bearing and public health, infancy and childhood, school health service, "certain noncommunicable diseases," namely cancer, heart disease, mental diseases and diabetes, and a closing chapter on medical care.

The book is clear, concise and packed with information. It should be serviceable as a desk manual for health officers and their administrative personnel, in the teaching of public health, and for the school administrator. Practicing physicians who will be brought increasingly in contact with public health procedures will find this book excellent to give them an understanding of the administrative point of view in public health.

The chapter on medical care is reminiscent of the Shakespearean curse "on both your houses." The author begins with a summary of the situation, for which he relies largely on the publications of the Committee on the Costs of Medical Care and the National Health Survey by the U. S. Public Health Service and other government sources; to these statistics many physicians have taken serious exception. Coming to the question of the private practice system of medical care, he pays tribute to it as a system of practice which "safeguards individual liberty, permits competition, free enterprise and freedom of choice in their most desirable forms. . . . There can be no doubt that for certain elements of the population in the United States this system has produced as fine medical care as anywhere in the world. Those who have benefited most by it are the fairly well to do and the rather completely poor. . . . It is those in the middle and the lower income brackets who have failed to benefit from this system of private medical practice." Those who would change the system are described somewhat caustically: "On the one extreme there is thrown into the argument the fervor of the reformer who burns with a zeal for betterment of those he considers underprivileged. . . . He is the kind of person who bleeds vicariously for humanity and hurls terms like bourgeois, tory and fascist at all who oppose him. . . . Not infrequently this type of person is a quite objectionable fellow." The author, however, is no kinder to the defenders of the present system of medical care: "On the other extreme . . . is the typical well fed, rather sleekly tailored specialist who by the tradition of his profession is more or less honor bound to defend the private practice of medicine as it is. He never sees the economically distressed except in an orderly hospital ward or in the white cleanliness of the operating room; and so far as he is concerned medical care of a high order is freely and amply available to all." There is more to both descriptions, but these excerpts will suffice. The author adds that "in all fairness it should be noted that each is sincere in his attitude. Fortunately, they are not indices of the public on the one hand or of physicians on the other; . . . they are the most vocal and to that extent appear as representative of their respective groups." The author's own attitude seems to be summed up in the statement "It is apparent that some sort of public medical service will, in the future, be developed. A contribution would be made if more level headed persons, representing physicians on the one hand and the public on the other, made themselves heard, to the exclusion of bitter and emotional voices."

Handbook of Chemistry: A Reference Volume for All Requiring Ready Access to Chemical and Physical Data Used in Laboratory Work and Manufacturing. Compiled and Edited by Norbert Adolph Lange, Ph.D., Assisted by Gordon M. Forker, B.S. With an Appendix of Mathematical Tables and Formulas compiled by Richard Stevens Burlington, Ph.D., Associate Professor of Mathematics at Case School of Applied Science, Cleveland, Ohio. Fifth edition. Cloth. Price, \$6. Pp. 1777; 271. Sandusky, Ohio: Handbook Publishers, Inc., 1944.

This is a handbook, as the title indicates, prepared with the assistance of various collaborators. The editor many years ago earned the confidence and respect of his profession and of those who require ready access to the chemical and physical data used in laboratory work and manufacturing. Several tables which appear in this edition for the first time have necessitated an increase in the number of pages. They are Periodic Table (Deming); Flammable Liquids; Flame Temperatures; Plastics; Fluorescence of Chemicals, Minerals and Gems; and Water for Industrial Use. Their contents will be welcomed by those engaged in that particular field. Many of the tables occurring in previous editions have been completely revised and brought up to date, thereby increasing the size of the volume. Previous books have proved to be of value not only to the chemists and chemical engineers working in manufacturing plants but to those employed in clinical and pharmaceutical laboratories as well. It is believed that this edition, with so many revisions of the various subjects and the additions of new data, will prove to be of greater value as a reference volume. The present volume is well compiled and printed on good paper. It is worthy of recommendation and should be on every scientific worker's desk or at least handy for consultation.

Practical Neurological Diagnosis with Special Reference to the Problems of Neurosurgery. By R. Glen Spurling, M.D., Clinical Professor of Surgery (Neurosurgery), University of Louisville School of Medicine, Louisville, Ky. (On Leave of Absence). Third edition. Cloth. Price, \$4. Pp. 237, with 100 illustrations. Springfield, Illinois, & Baltimore: Charles C Thomas, 1944.

In this edition of the compend on neurologic diagnosis there are three parts: The first discusses and describes the neurologic examination; this is done acceptably. The second part takes up the spinal fluid and is clearly and ably written. The third part discusses roentgen diagnosis in neurologic diseases. It includes plain films and ventriculographic studies of the skull as well as plain films of the spinal column. There are remarks about lipiodol, thorotrast and air visualization of the spinal subarachnoid space. The book is up to date and is highly recommended to medical students, general practitioners and men in the armed forces.

Endocrine Man: A Study in the Surgery of Sex. By L. R. Broster, O.B.E., D.M., M.Ch., Surgeon, Charing Cross Hospital, London. With a foreword by Sir Peter Chalmers Mitchell, C.B.E., D.Sc., F.R.S. Cloth. Price, 12s. 6d. Pp. 144. New York: Grune & Stratton Inc.; London: William Heinemann, Ltd., 1944.

This scholarly and well written book is divided into eleven chapters devoted to cell evolution in relation to instinct, instinct, heredity, evolution of species, physiology of the autonomic nervous system, the diencephalon, the functional evolution of the endocrine system, the endocrine system, the adrenogenital syndrome, symbiosis and parasitism, and the nature of man. The discussion of the adrenogenital system holds great interest for the clinician. It recounts in an interesting way the good teamwork done by Broster and his co-workers in the study of this problem. Aside from this chapter the book has no great interest for the man in private practice.

A Bibliography of Aviation Medicine Supplement. By Phebe Margaret Hoff, Ebbe Curtis Hoff, and John Farquhar Fulton. Publication No. 9, Historical Library, Yale Medical Library. Published by the Committee on Aviation Medicine, Division of Medical Sciences, National Research Council, Acting for the Committee on Medical Research, Office of Scientific Research and Development, Washington, D. C. Cloth. Price, \$2.50. Pp. 109. Springfield, Ill.: Charles C Thomas, 1944.

A Bibliography of Aviation Medicine appeared two years ago. This supplement has become necessary because of the phenomenal growth of medical literature on aviation medicine. A new subheading has been added on rehabilitation; otherwise the classification, arrangement and style follow the conventions observed in the original bibliography, with some minor changes and rather less subdivision. There are fewer historical items, and the section on special psychology has not been subdivided. This is a most useful addition to the bibliography in the field.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

VALUE OF ELECTROENCEPHALOGRAM IN EPILEPSY

To the Editor:—What is the value of an electroencephalogram in the diagnosis of epilepsy? With respect to grand mal, what percentage of patients show diagnostic recordings between attacks? When attacks are rare and diagnosis is in doubt, what is the actual value of a "normal" encephalogram?

M.D., New York.

ANSWER:—More than most laboratory procedures, the value of the electroencephalogram rests on dependable apparatus and on experienced interpretation of the tracings obtained. Under these conditions the electroencephalogram in most cases of epilepsy gives more pertinent information than all other laboratory procedures combined. The technic is most useful in confirming a diagnosis of epilepsy made on clinical grounds and in judging the type and severity of the accompanying cerebral dysrhythmia. Records made during a seizure are practically always abnormal and distinctive for the type of seizure which the patient is experiencing—grand mal, petit mal or psychomotor. Of tracings made between seizures, only one form can be considered diagnostic: the three per second alternate dart and smooth dome of petit mal (pyknolepsy). In a resting period bursts of high voltage fast waves such as are uniformly encountered during a grand mal seizure are found in only 1 per cent of patients with a history of grand mal only. Discharges of high voltage slow waves occur in 42 per cent of patients having a history of psychomotor seizures only, and the alternate dart and dome formation in 85 per cent of those having petit mal only. In the latter group, however, because of the frequency of petit mal, many of these records are made during a seizure. Approximately 15 per cent of patients with a clinical diagnosis of epilepsy have a normal electroencephalogram during a fifteen minute recording. This proportion is higher in patients whose seizures are rare. The presence of a normal electroencephalogram does not exclude a diagnosis of epilepsy any more than a single normal electrocardiogram excludes a diagnosis of heart disease or of paroxysmal disturbances such as extrasystoles or paroxysmal tachycardia.

NERVE TRAUMATIZATION IN TREATMENT OF POLIOMYELITIS

To the Editor:—A recent article in *Time* referred to the treatment of poliomyelitis by crushing the nerve above the point of muscular wasting. This form of treatment has been suggested by Lieut. Comdr. Harvey Ellsworth Billig Jr. (MC) and a physiologist, Anthony Van Harreveld of the California Institute of Technology. According to the report, this procedure of nerve crushing can now be done bloodlessly with an air driven rivet gun, and the *Time* article said that it has been performed on 500 patients in Los Angeles and 40 in Philadelphia with remarkably good results. A friend of mine who has a paralyzed son has asked me to find out the value of this treatment. The boy in question has been paralyzed in the right leg for a number of years.

Thomas M. Adams, M.D., Montezuma, Ga.

ANSWER:—The benefits to be derived from the operation described by Lieutenant Commander Billig, consisting in crushing a nerve above the point of muscular wasting in patients who have suffered from infantile paralysis, are not yet sufficiently proved for the procedure to be accepted by men who have had the greatest experience with the problem of paralysis following anterior poliomyelitis. The recently suggested procedure of traumatizing the nerve with an air driven rivet gun will require much more controlled study before it can be recommended. Trauma of any kind will produce varying degrees of hyperemia. Hyperemia is a reaction of repair. Such a reaction may be of some benefit in stimulating recovery of tissues which have been injured. No procedure carried out on peripheral nerves or other peripheral tissues can be of any value in regenerating or restoring destroyed anterior horn cells. The major pathologic change in paralysis from poliomyelitis consists in the damage to these anterior horn cells. For that reason, in the most cases at least, the approach to the problem is from the wrong direction when treatment is given to peripheral nerves. This treatment would be of doubtful value to the boy with paralysis in the right leg which had been present for a number of years.

ENDEMIC GASTROINTESTINAL INFECTION

To the Editor:—For three years, especially the past summer, I have had patients of all ages over a year report severe epigastric pain high in the abdomen, generally central although it may be to right or left or both sides. The pain may be accompanied by nausea and vomiting, diarrhea or loss of appetite. Distress follows food, cold drinks and laxatives; stooping and activity make it worse. Relief is obtained from intravenous feeding, rest and heat. The temperature is normal, the pulse rate 60 to 80 unless there is vomiting, and the white blood cell count is generally low (3,400 to 6,600). The urine is normal. There is no tenderness of the gallbladder nor pain in the back, as in pancreatitis. One child who had fecoliths in the appendix showed enlarged mesenteric glands. This condition may last four to six weeks and incapacitate the patient; there is a severe depression following the illness.

C. C. Hall, M.D., Maynard, Iowa.

ANSWER:—The symptoms and findings presented are not sufficient to permit an accurate diagnosis without further investigative procedures. The recurrence of similar symptoms for three summers and their occurrence in patients of all ages indicate an endemic infection of some sort. The common conditions to be considered are several: The symptoms are suggestive of an infection due to one of the Salmonella group of organisms. Culture of the patients' stools should be made; in the usual types of bacillary dysentery the diarrhea is more prominent and the leukocyte count higher than in the description given. The chronicity of the symptoms, low leukocyte count and pronounced depression are seen in undulant fever: the organisms may be found on culture; agglutination tests usually become positive after the first week of the disease. Mesenteric lymphadenitis suggested by the observation of enlarged glands in the case is not an entity but the manifestation of an intestinal infection. Careful bacteriologic study of the cases described is indicated.

TREATMENT OF PERIAPICAL INFECTIONS

To the Editor:—What is the consensus regarding treatment of apical abscess of teeth with sulfonamides, penicillin or other drugs versus extraction? In this particular case, the abscess is well determined by x-ray, seems to be $\frac{3}{8}$ inch in diameter, is well capsulated and is draining externally through a fistula of the gum. This condition has been present for approximately a year and seems to cause no discomfort except an occasional headache. The patient is willing to undergo treatment by drugs over an extended period if there is a fair chance of recovery.

Walter E. Kramer, M.D., Chillicothe, Ohio.

ANSWER:—Periapical infections arise as a result of dental infections within the root canal, and therefore the removal of the original source of infection is indicated. This may be done by proper root canal therapy or the extraction of the tooth. If root canal therapy fails, the tooth must be extracted. Chemotherapy may hold in check the tendency for serious bacteremia, but there is no evidence to indicate that such therapy is able to remove foci of infection.

A chronic infection as described is not painful, particularly when there is drainage through a sinus in the gum tissue. Studies have been reported on the direct application of the sulfonamides to infections in the teeth and periapical tissues. The consensus is that they are not as effective as the treatment dentists usually employ for these conditions. The use of penicillin is under study, but reports are too meager to permit conclusions. One thing is certain—chemotherapy will not cause spontaneous resolution of the abscess. If the latter is allowed to remain, it may extend to infect adjacent structures or even result in a local osteomyelitis.

MIGRAINE OR EPILEPSY

To the Editor:—A patient now past 60 at the age of 40 started having attacks without premonitory aura, during which his pupils dilated, partial blindness occurred and, according to his daughter, his eyes got "glassy." He has had no convulsions. Since the first attack he has had many others of varying degrees of severity. With the mild cases he has only impairment of vision, but with the severe ones he is disoriented; the attacks last from fifteen to forty minutes. Sometimes there will be intervals of freedom for several months, while at other times he will have two attacks in a half day. Headache invariably follows, sometimes attended with nausea; and a few times he has vomited and the headaches have lasted twenty-four to thirty-six hours. Is this petit mal, or is it migraine, or is it a combination of the two?

M.D., Texas.

ANSWER:—It is not petit mal (pyknolepsy); the retention of consciousness is against the diagnosis of any type of epilepsy. The evidence submitted favors migraine. This diagnosis is more likely if the partial blindness consists of scotoma or hemianopsia, if the headache which invariably follows is one sided, if there is a family history of migraine, if attacks are relieved by subcutaneous injection of ergotamine tartrate and if the electroencephalogram is normal. The age of onset is rather late for migraine, and disturbances in mental processes to the extent of disorientation are unusual. Possibly the usual physiologic cerebral vascular phenomena of migraine are complicated by pathologic vascular changes.

PENICILLIN THERAPY IN HEMOLYTIC STREPTOCOCCIC PHARYNGITIS AND TONSILLITIS

MAJOR NORMAN PLUMMER

MEDICAL CORPS, ARMY OF THE UNITED STATES
FORT BRAGG, NORTH CAROLINA

DOROTHY RHOADES DUERSCHNER, A.B.

MAJOR HAROLD DRAPER WARREN

CAPTAIN FRANCIS T. ROGLIANO

AND

CAPTAIN RUELL A. SLOAN

MEDICAL CORPS, ARMY OF THE UNITED STATES

Despite the advances in chemotherapy, the development of an effective treatment of such a relatively common disease as hemolytic streptococcic pharyngitis-tonsillitis remains an important medical problem. Although the clinical value of the sulfonamides first was demonstrated against the hemolytic streptococcus,¹ subsequent clinical observations have shown that this organism is relatively sulfonamide resistant when compared with the meningococcus, gonococcus and pneumococcus. Furthermore, some observers believe that the clinical courses of uncomplicated streptococcic pharyngitis-tonsillitis and scarlet fever are not alleviated or shortened by sulfonamide therapy,² although it is generally accepted that complications occur less frequently in these diseases when the sulfonamides are used³ and the value of the sulfonamides in the treatment of hemolytic streptococcic otitis media, mastoiditis, meningitis and pneumonia is unquestioned. Since the introduction of penicillin, the superiority of this new drug over the sulfonamides in the serious hemolytic streptococcic infections has been demonstrated⁴ but its value in acute pharyngitis-tonsillitis has not been ascertained.

Support and assistance were given by Col. Charles M. Watson, surgeon, Second Service Command; Col. A. W. Greenwell, surgeon, Fort Jay Regional Hospital, and Lieut. Col. Herman L. Blumgart, medical consultant, Second Service Command.

The laboratory investigations were carried out in the Department of Public Health and Preventive Medicine, Cornell University Medical College, under the Commission on Influenza, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Service, Office of the Surgeon General, United States Army.

Acute follicular pharyngitis, which is associated with acute follicular tonsillitis whenever the tonsils are present, is an accepted clinical entity and occurs frequently both sporadically and in epidemics, more commonly in children and young adults. Bacteriologic studies have shown it to be caused usually by the hemolytic streptococcus.⁵ The clinical diagnosis is made by the abrupt onset of fever and sore throat, and particularly by the appearance of the throat, the mucous membrane of which is red and edematous, with large follicles and irregular patches of exudate. The tonsils when present are enlarged, red, follicular and studded with irregular patches of exudate. The regional cervical lymph nodes are usually enlarged and tender. While the acute course may be short (usually two to five days), convalescence often is protracted, frequently requiring two to three weeks. The complications of hemolytic streptococcic pharyngitis are insidious in their inception, relatively frequent and often serious.

During the winter and spring of 1943-1944, bacteriologic studies⁶ in cases of respiratory disease in army and civilian hospitals in New York City and vicinity showed a 35.4 per cent incidence of cultures positive for the hemolytic streptococcus as compared with 5.8 per cent for the previous year. Also there was an increasing incidence of acute follicular pharyngitis and tonsillitis and, secondary to these conditions, many cases of peritonsillar abscess and a number of instances of hemolytic streptococcic pneumonia and empyema. Furthermore, several fatalities occurred in the locality, presumably due to a fulminating hemolytic streptococcic invasion. Because of the increasing seriousness of the problem, with an aim to decrease the number of complications and at the same time to shorten and alleviate the acute symptoms of a very painful disease, a trial of penicillin therapy was instituted.

The study was made at the Fort Jay Regional Hospital, which has an active acute respiratory disease service, and was commenced April 4, 1944. Only the severer cases were included, the criteria of selection requiring a temperature of 102 F. or above, a characteristic local lesion of redness, edema, follicular swelling and patches of exudate, a condition always accompanied by severe angina and moderate to severe systemic reaction. In addition, no patient acutely ill for more than thirty-six hours was included. On all patients, before the institution of any therapy, a complete blood count, urinalysis and a nasopharyngeal culture were made and blood was obtained for serologic study. The nasopharyngeal culture was repeated every day or every other day throughout the illness. Blood sulfonamide

6. These studies were made in connection with investigations on influenza being carried out by the Influenza Commission of the Board for the Investigation of Epidemic Diseases, United States Army.

determinations were made on all patients treated with sulfadiazine. These patients, in a rough way, were treated alternately with penicillin and either no specific therapy or sulfadiazine, 4.0 Gm. initially and 1.0 Gm. every four hours for an average total dosage of 25 Gm. The purpose of the alternation was to have a means of direct comparison, because at the onset it was appreciated that the series would be too small for a significant statistical analysis.

CULTURE TECHNIC

The bacteriologic method used was one with which we have had long experience and one previously described.⁷

A small cotton swab on a curved malleable aluminum wire is passed over the base of the tongue into the posterior nasopharynx. The swab is put immediately into a tube of 2 cc. of hormone blood broth, and the broth is quickly frozen by placing the tube in a vacuum jug containing solidified carbon dioxide. The specimens are ordinarily studied within a few hours of the time taken, but carefully controlled observations have shown no appreciable change in the cultures after having been frozen for as long as one month. When studied, the specimen is thawed promptly and under uniform conditions by being inserted in a water bath at 37 C. After the tube has been thoroughly shaken a measured amount of the inoculated broth is spread by an L shaped glass rod on blood hormone agar plates. After incubation for four hours, 0.5 cc. of the blood broth is injected intraperitoneally into white mice for a further check on the presence of the pneumococcus and other organisms considered significant. The blood agar plates are incubated and studied at twenty-four and forty-eight hours for the presence and distribution of organisms. The hemolytic streptococcus in addition to its appearance on the original blood agar plate is identified by gram stain, by subcultures in blood broth and on blood agar pour plates and finally by Lancefield grouping. The pneumococcus is identified in addition to cultural methods by the Neufeld typing. Hemophilus influenzae and the staphylococcus are recognized by their cultural and staining characteristics. Any other organism isolated through the mouse or present in large numbers on the original plate is identified whenever possible.

In the present study we have been particularly interested in the presence and number of hemolytic streptococci. In each specimen the total bacterial growth was graded as to whether it was 4 plus (largely confluent), 3 plus (innumerable, but mostly discrete colonies), 2 plus (50 to 300 colonies) or 1 plus (less than 50 colonies), and the proportion of hemolytic streptococci to the total bacterial growth was graded on a roughly numerical percentage basis.

CLINICAL CASES

Before analyzing the cases for the specific effects of therapy, a brief description of the clinical aspects of the group of cases as a whole seems important. Between April 4, 1944 and July 13, 1944 54 new cases were accepted for study. All the subjects were young men, hospitalized in the Fort Jay Regional Hospital. The smaller proportion of the group was made up of men posted at Fort Jay, the larger proportion of men stationed or residing in lower Manhattan and sent to the hospital by the Army General Dispensary. All of the subjects had temperatures of 102 F. or over and pronounced local involvement, as already mentioned, but had no evidence of complications.

Forty-four of the 54 patients had not had their tonsils removed and consequently also had acute tonsillitis. The 10 patients without tonsils had no complications

and the acute phase was comparatively short and mild, while among the 44 cases of acute pharyngitis and tonsillitis there were 4 of peritonsillar abscess, 5 of scarlet fever, 1 of pneumonia and 1 of scarlet fever complicated by acute sinusitis and pneumonia, and 1 in which subsequently a first attack of rheumatic fever occurred.

An unexpected feature of the hemolytic streptococcal infections was the slight increase or absence of increase in total white blood cell count. This occurred in most of the severer infections and even in cases of pneumonia and empyema and, in view of other reports, is difficult to explain.

BACTERIOLOGIC FINDINGS

In spite of the rigid clinical criteria used in the selection of cases, some occurred in which the cultures were negative for hemolytic streptococci. However, 45 (83.3 per cent) of the 54 cases showed group A streptococci, and of these 30 showed an almost pure culture. 9 showed definitely positive results (10 to 50 per cent of the colonies) and 6 showed only a few organisms. The 9 negative cases presented other organisms which may or may not have been significant. In 3, Hemophilus influenzae was the predominant organism, and in 4 the pneumococcus was isolated. In each instance the type was different, being 3, 4, 6 and 17 respectively.

Thirty-nine strains of hemolytic streptococci isolated from the same number of different individuals were typed by the Swift-Wilson-Lancefield precipitin method.⁸

Twelve, or 31 per cent, of the thirty-nine strains were type 19, 8, or 21 per cent, were type 36, 4 were type 3, and there were 2 each of types 1, 5 and 26 and 1 each of types 4, 8, 14, 17 and 30. Only 4 strains could not be typed with the anti-M serums available. It is interesting that in the group showing hemolytic streptococci there were 4 cases of scarlet fever, and each of these showed type 3 hemolytic streptococci.

CONTROL CASES

For comparison with the penicillin treated patients we observed and studied 17 patients not treated with penicillin, 11 of whom had sulfadiazine and 6 of whom had no specific therapy. These cases were designated as controls by a rough method of alternation carried out during the early part of the study in order to eliminate the pitfalls of clinical selection of cases.

Fifteen of the 17 "controls" had tonsillitis as well as pharyngitis. There were no cases of scarlet fever. There were 2 cases of peritonsillar abscess, 1 after six and one-half days of sulfadiazine and the other in the "no specific therapy" group. Other than the peritonsillar abscesses there was no instance of clinical relapse. In the 15 uncomplicated cases the febrile period lasted from two to six days; however, the average period was three days. No differences were detected between the clinical courses of the strict controls and those of the sulfadiazine treated cases. However, a much larger series would be necessary to obtain information on the differences in the incidence of complications.

Bacteriologically, the cases were studied by frequent nasopharyngeal cultures made over periods lasting from seven to eighteen days. In 5 of the 6 cases in which no specific therapy was given, the initial culture showed many hemolytic streptococci, and this persisted throughout the acute illness. In 1 case the culture was negative on the eleventh day, and in 3 others it was still positive on the thirteenth, fifteenth and eighteenth days respec-

8. The typing was done through the kindness of Dr. Colin M. MacLeod, director of the Pneumonia Commission, Board for the Investigation and Control of Influenza and Other Epidemic Diseases of the Army.

tively. In 1 instance, with only a few hemolytic streptococci in the initial specimen, it was negative on the second day, slightly positive on the fifth day, negative on the seventh day and slightly positive on the ninth day. The sulfadiazine treated cases showed a pattern which we have already described.⁹ During the course of therapy the hemolytic streptococci (as well as the total organisms) in the nasopharynx are reduced in number, but only in 1 of the 8 cases of this series showing many hemolytic streptococci in the initial culture did these organisms disappear, and in all cases they returned with the discontinuation of sulfadiazine. Only 2 of the entire group of seventeen patients had negative cultures in the twenty-four hour specimen. Both of these showed a few colonies on the control plate and in broth, the following culture becoming positive. The final culture (made in seven to eighteen days from the onset) was positive in all but 3 of the cases, and these showed few hemolytic streptococci in the beginning. Examples of the clinical course and bacteriologic findings following no specific therapy and following sulfadiazine are shown in charts 1 and 2.

Chart 1 (control case).—Clinical course and results of nasopharyngeal culture in uncomplicated pharyngitis-tonsillitis treated symptomatically but without specific therapy.

EFFECTS OF PENICILLIN

For our first trial of penicillin it was decided to use a dosage of 15,000 units intramuscularly every four hours, continuing the therapy for approximately three days, a period roughly corresponding to that during which sulfadiazine ordinarily was given.

After treatment of a very few cases it became evident that there was a striking immediate clinical response to penicillin. In eight to twelve hours after the first injection improvement in the patient's condition usually was noticed. In twenty-four hours, as a rule, the patient was free from symptoms and usually had a normal temperature. The rapid retrogression in the pharyngeal involvement was the most amazing feature of the study. Usually by thirty-six hours the exudate, swelling and redness had entirely disappeared and the pharynx appeared normal. The bacteriologic change also was impressive. In twenty-four hours either very few or no hemolytic streptococci were cultured from the nasopharynx, and in forty-eight hours a negative culture was the rule.

⁹ Cecil, R. S.; Plummer, N., and Smillie, W. G.: Sulfadiazine in the Treatment of the Common Cold, *J. A. M. A.* 124:8 (Jan. 1) 1944.

These results were impressive, but we soon discovered that this was not the entire story. Of 9 patients who received penicillin for the three to four day period 4 showed both a bacteriologic and a clinical relapse which was almost as spectacular as the initial response. In these cases, twenty-four hours after peni-

Chart 2.—Sulfadiazine therapy. Clinical course and results of nasopharyngeal culture in uncomplicated pharyngitis-tonsillitis treated with full dosage of sulfadiazine. The hemolytic streptococci in the nasopharynx were suppressed but not eliminated.

cillin was stopped, a few hemolytic streptococci were found in the nasopharynx. Forty-eight hours later they were present in large numbers and concomitantly a return of the pharyngeal swelling, redness and exudate occurred. In 2 instances the recurrent signs and symptoms were as pronounced as at the onset. Charts 3

Chart 3.—Penicillin therapy for sixty-four hours: Clinical course and bacteriologic findings in pharyngitis-tonsillitis treated with penicillin for sixty-four hours. In the twenty-four hour culture hemolytic streptococci were not found on the blood agar plate but were isolated by mouse inoculation. The three day culture was entirely negative. Forty-eight hours after discontinuing penicillin there was a recurrence of signs followed by fever and a reappearance of hemolytic streptococci in large numbers in the cultures.

and 4 show the clinical courses and bacteriologic results in 2 of the patients having relapses following the discontinuation of penicillin, 1 having been treated for sixty-four hours and the other for ninety-two hours.

Five of the 9 patients receiving the three to four day penicillin therapy had no clinical recurrence, and it is interesting that in none of these did the nasopharyngeal cultures show a return of the hemolytic streptococcus. These five good responses were by patients with tonsillitis as well as pharyngitis, and one was associated with severe scarlet fever.

Chart 4—Penicillin therapy for ninety-two hours: Clinical course and bacteriologic findings in pharyngitis tonsillitis treated with penicillin for ninety-two hours. The nasopharyngeal culture, which before penicillin showed a heavy growth of almost purely hemolytic streptococci, after twenty-four hours showed only a few colonies (less than 50) and no hemolytic streptococci. Twenty-four hours after discontinuing penicillin hemolytic streptococci were isolated by mouse inoculation and on later cultures were present in almost pure culture. Simultaneously, a mild clinical relapse occurred. The patient was discharged on the thirteenth day of illness, the culture on the preceding day continuing to show hemolytic streptococci. Three weeks after discharge the patient returned with a severe first attack of rheumatic fever. The nasopharyngeal culture on this admission showed no hemolytic streptococci.

The initial response followed by a high rate of recurrence suggested to us that penicillin, perhaps while temporarily controlling the infection, interfered with the normal development of immunity. Therefore we decided to try using penicillin for a shorter period, believing that in this way there might be no interference with the natural spontaneous immunization and at the same time a favorable modification of the clinical course.

Nine patients were given penicillin for a twenty-four hour period, 6 receiving 150,000 units total dosage; 3 received 100,000 units, together with routine sulfadiazine therapy. In each group there was 1 case of acute peritonsillar abscess. While the twenty-four hour nasopharyngeal cultures were negative on all except 1 of the patients, the hemolytic streptococci regularly returned in all except 1 case. The clinical course and bacteriologic results in a patient given 150,000 units of penicillin are given in chart 5. This shows also the effect of penicillin on a patient with peritonsillar abscess.

Because the clinical and bacteriologic results had not been at all striking following a twenty-four hour course of penicillin, it was decided to investigate the response to penicillin in the dosage of 15,000 units every four hours, extending the course of therapy to six days. Ten cases are included in this group, and the results are uniformly favorable, except in 1 instance. Nine showed no signs nor symptoms, and all of the cultures were negative after thirty-six hours of therapy. When penicillin was discontinued after six days, the cultures apparently remained negative for hemolytic streptococci and there was no return of symptoms and no later

development of any complication. An example of this clinical and bacteriologic response to penicillin is shown in chart 6.

The course of the 1 exceptional case (chart 7) in this group is most instructive:

W. F., aged 22 years, was admitted to the hospital on May 28, 1944, having had nasal congestion and slight malaise for thirty-six hours. On May 29 his temperature rose to 103.8 F. and he complained of severe sore throat and difficulty in swallowing and breathing. The pharynx was much injected and edematous; the tonsils were large, cryptic and spotted with exudate; the cervical nodes were slightly enlarged and tender. The remainder of the examination was negative. There was no rash. The white blood cell count was 31,600, with 92 per cent neutrophils, 7 per cent lymphocytes and 1 per cent monocytes. Urinalysis was negative.

Penicillin, 15,000 units intramuscularly every four hours, was started about twenty hours after the onset of acute symptoms and was continued for six days (540,000 units). Shortly after penicillin was started the patient developed a pronounced scarlatinal rash, which disappeared in about thirty-six hours. The nasopharyngeal culture made at the start of therapy showed a heavy growth of colonies, 50 per cent of which were group A hemolytic streptococci identified as type 3 (Lancefield). Twenty-four hours after penicillin was started the culture was negative for hemolytic streptococci and remained negative throughout the course of therapy. Twenty-four hours after penicillin was discontinued the culture showed hemolytic streptococci by mouse inoculation and following this, in cultures, they appeared in increasing numbers. With the return of the hemolytic streptococci, first acute purulent sinusitis and then acute pneumonia developed. These conditions were confirmed by x-ray examinations. The patient's condition was not critical at the time of the complications; consequently penicillin therapy was not resumed.

COMMENT

This study, like many other scientific investigations, answers a few questions but poses many more. We have evidence that penicillin, if given over a sufficient period of time, will shorten and alleviate the acute symptoms

Chart 5—Penicillin therapy for twenty-four hours. Clinical course and results of nasopharyngeal culture in pharyngitis tonsillitis treated with penicillin (150,000 units) during first twenty-four hours of illness. For forty-eight hours the clinical course was satisfactory, the twenty-four hour culture showing no hemolytic streptococci. However, a severe peritonsillar abscess (left) developed by the eighth day and disappeared completely during a four day course of penicillin therapy. The patient was discharged but returned eight days later with a recurrence of the left peritonsillar abscess. This was drained and in three days was followed by a severe right peritonsillar abscess, which was treated also by incision and drainage.

of hemolytic streptococcal pharyngitis-tonsillitis. There is some indication that complications of this disease can be prevented and effectively treated. Our most striking

observation is the effect of penicillin on the hemolytic streptococcus in the nasopharynx. What causes it to disappear? Is it the bacteriostatic action of penicillin? What role is played by the body's immune mechanism? Is there a possibility of eradicating completely the hemolytic streptococcus from the body? If so, what effect might this have on the course of the disease and on

these cases we were not convinced that the organism isolated was the causative agent of the disease. Anti-streptolysin titers of the blood may give an answer to this problem.

Finally, 38 cases showed many colonies of hemolytic streptococci and in 30 of these it was found in almost pure culture. In these cases there seemed little question about the etiology and in these penicillin showed its most striking effect. A most convincing demonstration of the efficacy of penicillin is to contrast the twenty-four hour culture of a treated patient with the initial culture when this has shown a heavy growth of hemolytic streptococci. Of 25 such cases 21 were negative, 3 were "slightly" positive and in only 1 was the blood plate of the twenty-four hour culture "appreciably" positive.

A uniformity and consistency in the bacteriologic patterns was obtained throughout the study. The nasopharyngeal culture was found preferable to the pharyngeal culture, particularly because the plates were less contaminated with mouth organisms. The nasopharyngeal specimen must be procured by a person experienced in this procedure, and all steps of the laboratory routine must have the constant attention of an experienced bacteriologist. The determination is not presented as strictly quantitative but as roughly quantitative and, used this way, the end points are accurate. Many determinations have been made on the same specimen and a few checks on the same patient and only the expected slight discrepancies have been found. Furthermore, each case, treated or control, shows a pattern in the serial cultures and these have shown a well defined uniformity. Again, following the discontinuation of penicillin in cases in which the hemolytic streptococci return to the nasopharynx, the serial cultures follow a pattern. A few organisms may be found twenty-four hours later; a heavy growth does not occur for forty-

Chart 6.—Penicillin therapy for six days. Clinical course and bacteriologic findings in pharyngitis-tonsillitis treated with penicillin for six days. Treatment was started twenty-four hours after onset, when temperature had risen to 104 F. with the swelling and edema of the pharynx and tonsils becoming extreme. The clinical response was rapid. The hemolytic streptococci disappeared from the nasopharynx and had not returned seven days after penicillin was discontinued.

the occurrence of rheumatic fever or glomerulonephritis? From this preliminary study we do not presume to have the answers to all these questions.

On the basis of bacteriologic findings, the 54 cases of the study may be divided into three groups. First is a group of 9 cases in which no hemolytic streptococci were found in the cultures. In each of these at least four nasopharyngeal cultures were taken, in 1 eleven cultures, and all were negative. In several instances the pharynx, the exudate and the tonsillar crypts were cultured in addition to the nasopharynx but still no hemolytic streptococci were found. It is true that 6 of these patients received penicillin, and on the basis of our observations this may explain some of the subsequent negative findings. Clinically these patients were in no way distinct, and the local conditions were so pronounced that it has been difficult to explain the negative cultures. The pneumococci or *Hemophilus influenzae* isolated in these cultures may have produced the disease, but this does not seem likely because of the nature of the infection.

In a recent report on endemic exudative pharyngitis and tonsillitis¹⁰ in which the mild as well as the severe infections were studied, only 25 per cent showed beta-hemolytic streptococci in the pharyngeal culture and also exhibited a rise in titer of streptococcus antibodies during convalescence.

The second group includes 7 cases in which the findings were "slightly" positive. In 3 of these no colonies were identified on the plates but the group A streptococcus was obtained by mouse inoculation. In

Chart 7.—Penicillin therapy for six days. Clinical course and bacteriologic findings in pharyngitis-tonsillitis and scarlet fever treated with penicillin for six days. Following discontinuation of penicillin, hemolytic streptococci returned to the nasopharynx, and hemolytic streptococcus sinusitis and pneumonia developed subsequently.

eight to seventy-two hours. In our study the consistency of these changes was impressive.

Our observations show that the frequency with which hemolytic streptococci return to the nasopharynx is dependent on the duration of penicillin therapy. While 7 of 9 patients treated for twenty-four hours showed a return of hemolytic streptococci, 4 of 9 treated three

10 Commission on Acute Respiratory Diseases: Endemic Exudative Pharyngitis and Tonsillitis: Etiology and Clinical Characteristics, J. A. M. A. 125:1163 (Aug. 26) 1944.

to four days became positive, and in only 1 of 10 given penicillin for six days were the cultures again positive. The 4 clinical relapses of pharyngitis-tonsillitis, 2 peritonsillar abscesses and 2 post-tonsillitis hemolytic streptococcal pneumonias occurring in the penicillin treated cases all followed a return of hemolytic streptococci in large numbers to the nasopharynx. On the contrary, 15 patients with negative cultures following the cessation of penicillin had no complications. Taking the group as a whole, complications developed when the cultures were "strongly" positive and did not occur with negative cultures. These findings afford evidence that serial nasopharyngeal cultures can be a guide to prognosis and to penicillin therapy.

The occurrence of clinical relapse in 4 of the 9 patients who had received penicillin over a three to four day period deserves particularly careful consideration. There was no similar case among the control or sulfadiazine treated patients or among those who had penicillin for a single day. On the other hand, in no instance did a relapse or complication develop during the time the penicillin was being administered. Several times during the past winter we have observed post-tonsillitis hemolytic streptococcal pneumonia and empyema develop in the face of adequate sulfadiazine therapy, and there have been a number of similar instances of peritonsillar abscess which occurred while sulfonamides were administered. These observations demonstrate the greater efficacy of penicillin against the hemolytic streptococcus. The effect may be so great that one can speculate that the natural immune response may be interfered with and that it is necessary either to eradicate the hemolytic streptococcus or to allow more than the usual time for the development of a protective immunity.

Much immunologic investigation remains to be done in connection with the use of penicillin in this disease. It is of practical value to appreciate the greater effectiveness of penicillin and that it should be used without delay in any serious, progressive hemolytic streptococcal infection.

SUMMARY AND CONCLUSIONS

1. Fifty-four patients with severe acute pharyngitis-tonsillitis were studied clinically and bacteriologically. Forty-five of these had cultures positive for group A (Lancefield) hemolytic streptococci and were suitable for making a comparison of different therapeutic measures.

2. In 28 of the 45 positive cases, penicillin was given intramuscularly in a dosage of 15,000 units every four hours over periods varying from twenty-four hours to six days; sulfadiazine was given in 11 cases and no specific therapy in 6.

3. Penicillin was found to exert a pronounced effect on the number of hemolytic streptococci in the nasopharynx. The culture made twenty-four hours after the start of penicillin was almost always negative, and the serial cultures during the course of therapy remained negative. When penicillin was discontinued, hemolytic streptococci tended to return gradually to the nasopharynx. The frequency of their reappearance in our cases was inversely proportional to the length of time the drug was administered.

4. In 19 patients treated with penicillin for sixty-four hours or more symptomatic relief commenced in eight to twelve hours after the beginning of therapy and was complete in twenty-four to thirty-six hours. However, clinical relapse of the pharyngitis-tonsillitis occurred in 4 of the 9 patients treated for less than four days but

in none of the 10 treated for six days. One patient treated with penicillin for six days subsequently developed acute hemolytic streptococcal sinusitis and pneumonia. Throughout the study relapses and complications always were associated with the presence or reappearance of hemolytic streptococci in the nasopharynx.

5. This study reveals further evidence of the high antihemolytic streptococcal action of penicillin and emphasizes its value in dangerous hemolytic streptococcal infections. Penicillin in minor hemolytic streptococcal infections may be beneficial, but further investigation will be required to ascertain its exact indications and contraindications in these conditions.

NATIONAL HEALTH BASED ON LOCAL HEALTH UNITS

HAVEN EMERSON, M.D.

AND

REGINALD M. ATWATER, M.D.

NEW YORK

It is almost two years to a day since the House of Delegates of the American Medical Association resolved "That the Trustees be urged to use all appropriate resources and influences of the Association to the end that, at the earliest possible date, complete coverage of the national area and population by local full time modern health services be achieved."

Resolutions of identical intent were passed by the American Public Health Association in October 1942 and by the Conference of State and Provincial Health Authorities of North America in March 1944. Since the creation in August 1942 of a Committee on Local Health Units of the American Public Health Association, considerable progress has been made in assembling pertinent facts and in obtaining consideration and support from state health officers for a pattern of local health services which gives promise of a reasonable satisfaction of the resolution as soon as medical, nursing and engineering personnel can be returned from the military to the civil needs of our people.

A progress report of the committee was published in the April 1943 issue of the *American Journal of Public Health* in which will be found the description of the existing inadequacy of local health services in continental United States and provisional suggestions for 1,127 local health jurisdictions to cover all the states, such units to be of single or several counties, city-county or districts, the latter including parts of one or more counties.

After correspondence and personal conference with the health officers of thirty of the states it was found, after adding a few districts in some states and consolidating areas in other states on the recommendation of the respective state health officers, that 882 local units were agreed on, the same number for these thirty states as originally suggested by the committee, although not in all instances the same number in each state as originally proposed.

It appeared then that the basic proposals as to size of area and population and in respect to necessary medical and associated personnel for such local health units were acceptable at least in principle to those officers of state government whose attitude toward the complete

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Fourth Annual Session of the American Medical Association, June 16, 1944.

coverage of their states with local health services would be a determining factor in further progress.

At the present writing agreement as to the desirability of such local health units and agreement as to number and boundaries in the respective states has been received from forty-two of the states.

Until further consideration with the health officers of the other six states has adjusted pending differences of opinion as to details of size and number of the local health units suggested by the committee, a definitive number of units for all forty-eight states cannot be presented, but it would appear that approximately 1,197 such local units will be sufficient, economical and efficient for the needs of the nation.

The next step would appear to be the listing of existing full and part time personnel now employed in local health services in each of the proposed units and of the salary and total costs of maintaining such facilities as now exist, supplemented by a description in similar detail of the desirable personnel and estimated costs of a balanced and adequate modern health service under a trained full time medical officer of health.

Information of this kind is being obtained from federal, state and local sources and will be presented in a report of the committee to be published early in 1945 in such form as to be easily understood by officers of local and state government and by voluntary citizen organizations, and local and state medical societies.

From studies made available to the committee through the courtesy of the U. S. Public Health Service, it appears that existing laws in thirty of the states make possible by one procedure or another the creation of such local health units as we are considering, but few if any state statutes cover each of the essentials of permissive legislation required.

A special committee of the National Conference of Commissioners on Uniform State Laws is now preparing a draft of such legislation as would be desirable generally among the states to provide the necessary authority for creation of such districts as are proposed, and to safeguard the qualifications of professional and other personnel, to secure tenure of office during competent behavior, and to permit or require the raising of tax monies sufficient to support such local health departments.

It is expected that state and county medical societies will inform themselves as to the local units of health service approved by the state health officer, familiarize themselves with the need for enabling legislation, if any, support such appropriate laws as are before their legislature for this purpose, and share with other influential bodies of public opinion and action that are interested in achieving adequate modern local health service under full time professionally expert medical direction. Up to the present time the strongest favorable influences appear to be those of farm families and organizations representing them, and the agricultural colleges of state universities. No opposing interests have developed, unless we consider in some states a passive resistance to change by the large numbers of part time lay and medical health officers of villages and towns, to replace whose services by those of trained public health personnel is one of the major objects of the proposed units. Only at real sacrifice of time and money can a busy medical practitioner in his spare time serve the indispensable purposes of public health officer.

There are not less than 38,000 units of local government in the United States and there are apparently

about 10,000 communities of small size and small resources whose only representative of health service is a layman appointed or elected to other office and serving ex officio, without any special qualification for his duties.

It has been said on good authority that, at the present rate of progress in developing full time county health services for the 3,070 counties of our states, it will take more than a hundred years to cover our nation with such local health services. Many counties are too poor in population and resources to maintain a good single county health department.

The resolutions referred to and the apparent acceptance of the principle of units of local health service as presented by the committee of the American Public Health Association seem to demand progress more swift and practical.

With local units of government of the size and character proposed, each provided with medically trained and professionally expert leadership through full time health officers, assisted by public health nurses in the ratio of 1 to each 5,000 of population, with at least one public health engineer and suitable numbers of field sanitarians, and with appropriate clerical personnel, the state departments of health will be able to develop to a higher grade their own proper supervisory consultant, advisory and central staff functions, on a statewide basis, and the federal health services can concentrate on interstate and international public health matters, for which they are well qualified.

The two sources of most powerful potential influence for the establishment of competent local health services for all the people of our nation, in addition to the support of the body of professionally interested workers in existing civil health departments, are the members of the American Medical Association through their county, district and state or national organizations, and the lay and professional members and supporters of local, state and national volunteer health agencies, such as are included within the National Health Council. While the original or inciting resolution, initiated by this section, has been followed by sympathetic action in the House of Delegates and by appropriate editorial support in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, no overt action to make the influence of the American Medical Association effectively felt publicly has been reported from the Trustees. Nor has any state medical society accepted the opportunity of exercising its influence for national health by organizing the favorable opinion of its members through standing or special committees with respect to the number, boundaries and services of local health for its state.

Public health services at the local level are to a great extent of a personal nature, directly related to the private practitioner of medicine and to his patients. These services are best provided where the local communities served are well informed about and prepared to take their share in the support of health functions through their elected officers of local government.

A medical officer of health is today as much a specialist in the application of the medical sciences for public protection against disease as any of the clinical specialists in medicine and surgery are specialists in their respective fields.

Professional graduate education and practical experience training for the administrative and leadership responsibilities of a medical officer of health are in the main as exacting, time consuming and expensive as are similar preparation for a career in most of the clinical specialties.

Rarely can a community or a group of neighboring communities with less than about 50,000 population in one or more counties support a qualified medical officer of health and the necessary associated personnel.

It is in the best interests of national health and the best interests of the medical profession that local units of government be authorized and organized to provide good health services under medical leadership.

The facts are at hand on which sound policies can be based. An acceptable pattern for local health services has been favorably received by the public health professions. Active systematic, sustained support of the American Medical Association, such as was given over a period of thirty years on behalf of model vital statistics laws and their enforcement, is now needed to bring about the achievement so well and unanimously voiced by the House of Delegates two years ago.

600 West 168th Street.

ABSTRACT OF DISCUSSION

DR. RICHARD F. BOYD, Springfield, Ill.: It is generally recognized that in order to experience a satisfactory increase in the number of full time adequately staffed county and multiple county health departments several factors are involved. First of all there must be legislation permitting the establishment and maintenance of such health departments. In Illinois such a statute was enacted in 1943. This law was carefully prepared after consultation with leaders in the public health field and appears to be quite adequate to meet this need. The interest and active support of professional groups is also a necessity if a satisfactory growth of local health service is to develop. This interest has been evidenced in Illinois by the strong support of the state medical, dental and public health associations at the time at which the legislation mentioned was obtained. There is every indication that this support will be enjoyed by the county and multiple county health departments when they come into existence, since representation of the medical and dental groups on local boards of health is provided by law. Interest of the populace in general is also necessary to the growth of local health departments. This interest has been manifested by the organization of a statewide public health committee in Illinois for the purpose of promoting better public health services and by the endorsement of the county health law by many statewide organizations. There must be also a definite plan of development, as outlined by Drs. Emerson and Atwater. A plan for the establishment of twenty-seven single county and thirty-two multiple county health departments was submitted to and approved by the Committee on Local Health Units of the American Public Health Association, to which reference was made by the authors of this paper. This plan is now in the process of implementation by the Illinois Department of Public Health assisted by the aforementioned professional and lay groups. Three county health departments have been established under the new county health law. Two of these counties were previously organized on a war emergency basis, while the third has had no prior experience with local health work as carried on by county health departments. Having met the criteria as outlined, and judging from the action of these counties in establishing health departments under the provisions of the new law, it is believed that we may expect a satisfactory growth of adequately staffed county and multiple county health departments during the next several years, resulting both from the reorganization of existing health departments established on a war emergency basis as well as the establishment of health departments in previously unorganized counties.

DR. FELIX J. UNDERWOOD, Jackson, Miss.: In my state, of the eighty-two counties sixty-five have full time county and district health departments; but for the war, all eighty-two would have been organized by this time, I am sure. Mississippi is a small, poor state but a state that is tremendously interested in public health. When I was a county health officer a number of years ago in a county with a population of less than 40,000, I observed how the city health officer of the principal town,

the county seat, with a population of only 5,000, and the county health officers were wont to pass the buck from one to the other. Too frequently when I was approached about a problem within the confines of the city I would say "This is within the city limits, you see, so you should see Dr. So and So about that" (the city health officer). Then the city health officer would say "After all, Aberdeen is in the county, and the county is over all, therefore the county health officer should attend to this." And most of the time the matter wasn't attended to without a lot of passing of the problem back and forth. I am glad to see that condition corrected to a great extent, and, having one department responsible for carrying on the health work in the area, one can place responsibility. I am glad to see so much duplication of effort and overlapping being done away with, as it will be more and more as this plan is developed to perfection. We are dropping a lot of politics too as we go along. That has been the bane of our existence in the past, but it is less and less so as the years pass. Think of the attitude of Congress toward public health today as shown by appropriations for public health purposes! Think of the attitude shown by the several state legislatures by their being willing, sometimes quite willing and anxious, to make proper appropriations for the furtherance of public health work! Think of the county boards of supervisors and the mayors and councilmen of our cities! Never before have we seen such a manifestation of confidence and belief in public health in this country. It is up to us. I believe we are meeting the challenge quite well. I think we are on the eve of the greatest public health development in this country that we have ever seen, and that will come in postwar days when personnel can be had. There will be no further trouble about money and less trouble about politics, I think.

DR. GILBERT COTTAM, Pierre, S. D.: We in South Dakota are in the embryonic stage just now. Only within the last few months have we even formulated a plan and sent it in to be considered. I wasn't very strongly sold on it at the start. I had been a surgeon for a number of years, and when I came into public health I didn't know much about it. But it is a tremendous problem, and in a state like South Dakota, where right now we are facing a situation of shifting population, we have new areas which have grown up around war industries and we don't know whether they are going to be permanent or not. So we cannot predicate plans definitely until we know for sure; however, we are doing the best we can and we have sent our plan in, dividing the state up into fifteen districts. We have now only two full time health units in the state, one a county unit in the eastern, well populated part of the state, and another in the Black Hills area, both working well and serving as splendid models for the future. This winter, when our state legislature meets, I hope to be able to go before it with enough information to show it the value of this sort of thing and get enough support so that then with the help that we shall get from the federal government we shall be able to do something.

DR. JAMES R. SCOTT, Santa Fe, N. M.: I think New Mexico was one of the first states that developed the system of district health. We have been operating since 1935. I was glad to hear from Drs. Emerson and Atwater's paper that they are going ahead to develop legislation making permissible the establishment of these district health offices. If Drs. Emerson and Atwater want to learn several mistakes to avoid, I can supply them with several that made possible the district health work in New Mexico. We are handicapped by being about the fifth largest state in the Union in extent of mileage, and we have ten districts. Our population is widely scattered except for a few centers of population. It is essentially a rural state. I do not know whether Mississippi is poorer than New Mexico, or vice versa. We also are financially embarrassed. We expect, perhaps in the legislature which meets in January, to attempt to revise the public health act, known there as the District Health Act. The main feature of our work is that we are extending certain types of public health endeavor to a much larger percentage of the population than was true under the old county setup; however, we are not doing anywhere nearly a complete job. When you consider that one district health officer in New Mexico has a territory in geographic extent which is equal to the entire New England states omitting Maine, you

can see that we made some mistakes in setting up our districts and they, unfortunately, were embodied in the District Health Act, and to unscramble that act will take action of the legislature.

DR. JOSEPH W. MOUNTIN, Washington, D. C.: Failure on the part of local governments to function effectively in service fields is not due to lack of appreciation of human needs; rather it may be attributed to defects that are inherent in the structure of local government. If a unit of government is to render the comprehensive kind of service that makes up a suitable public health program, it must possess certain attributes. First of all such a unit must have a statutory basis for its existence, including powers of taxation and law enforcement, and it must have authority to operate essential facilities and services. Second, the size of the population and of the tax resources must be sufficient to assure economical operation and stability of financial support. In the continental United States there are some 38,350 units of local government, exclusive of school and improvement districts. They range in population from a dozen or so inhabitants to several million. More than 20 per cent of the country have less than 10,000 inhabitants. Obviously the smaller political units do not constitute suitable health jurisdictions. If health services are to be administered locally, and I believe it is quite generally agreed that this for the most part is desirable, the question of forming suitable administrative units must be faced frankly, and I might even say heroically. Appropriate combinations of preexisting political units may be the answer to the problem, but if this arrangement does not prove feasible some other scheme must be devised. I think the Committee on Local Health Units under the chairmanship of Dr. Emerson has done a masterly job. The committee has mapped the entire country into logical health jurisdictions and secured almost complete agreement on the part of state health officers. The more difficult job still remains of making these theoretically desirable districts political realities. Until this has been accomplished we shall not have a firm foundation on which to build a suitable local framework for carrying the expanding program of public health.

DR. REGINALD M. ATWATER, New York: Dr. Underwood of Mississippi, who is president of the American Public Health Association, has spoken of the complete coverage in public health which Mississippi enjoys. Let me point out that one of the reasons for this complete coverage grows out of the close linkage between the state medical society and the Mississippi State Department of Health. It would be a splendid arrangement if each state medical society took the initiative with its state health department to see to it that each state had a comprehensive plan for complete coverage. This would be in line with the resolution of the American Medical Association.

Public Health in Korea.—Public Health is under the direction of the sanitary section of the police bureau of the government general. Plans are made in the office of the government general and proceed through provincial and county officials to the local police. A civilian health officer and two assistants usually are assigned to each of the thirteen provinces. One physician or more and a number of nurses are stationed at each provincial hospital, however, and work that is not handled by the local police and police physicians is carried on by this provincial health staff. The officially defined duties of the provincial health staff, working with the police, include arrangements for clinical tours by provincial hospital physicians, quarantine inspection at all ports, inspection of water, food and drugs, control of epidemic and endemic diseases, inauguration of measures for the control of opium and leprosy, and veterinary problems. In practice, although regular tours by the full time provincial physicians actually are carried out at intervals through the year, the great majority of contacts with the masses of the population are made by police physicians. These physicians receive a small monthly salary for part time official services and are allowed to carry on a private practice at the same time. Usually the police physicians are found only in what respond to county seats. Practically all physicians engaged in public health work in Korea are Japanese.—Simmons, James S., and others: *Global Epidemiology*, Philadelphia, J. P. Lippincott Company, 1944.

THE TREATMENT OF PREMENSTRUAL DISTRESS. WITH SPECIAL CONSIDERATION OF THE ANDROGENS

S. CHARLES FREED, M.D.

SAN FRANCISCO

Relatively little attention has been paid by most physicians to the distress that many women undergo during the premenstrual period which usually disappears with the onset of menses. The disturbance at this time of the ovarian cycle has been termed premenstrual tension. The symptoms arising here are varied in character and in intensity and occur in various combinations, the most common complaints being nervousness, irritability, depression, emotional instability, headache, nausea and a feeling of tenseness. The most common signs are bloating of the abdomen and subcutaneous edema. In addition, patients may complain of a feeling of tightness of the skin, pruritus and swelling of the vulva and gastrointestinal disturbances such as vomiting, diarrhea or cramps. Occasionally one encounters bizarre manifestations such as premenstrual coma, convulsions, nymphomania and arthritic and neuritic pains. There is often observed, however, an aggravation of conditions which have little relation to ovarian function, such as asthma and hay fever, dermatologic lesions and quite commonly psychiatric difficulties. Apparently it is only when these symptoms produce extreme suffering that the physician is confronted with them, and it is often the psychiatrist who is first consulted. It is quite possible that the reason for this general unawareness for such changes is the acceptance by the woman herself that these disturbances are the normal part of a woman's fate and thus she makes little effort to seek relief unless they are severe.

Frank¹ was first to call particular attention to the syndrome of premenstrual tension. Israel² reported a number of cases of this disturbance, and the reader is referred to his article for a detailed description of typical cases. Greenhill and Freed³ pointed out the widespread occurrence of less intense degrees of this condition, which they designated as premenstrual distress. They postulated that there is a common etiologic factor for the two conditions, the difference between the two being quantitative. They maintained that these different and often unusual reactions result from a single metabolic change, namely the retention of sodium by the tissues induced by the sex steroids operating during the premenstrual phase. This retention of sodium is associated with an increase in extracellular fluid, so that the swelling of the various tissues gives rise to the respective symptoms. Thus, edema of the intestine induces nausea, of the brain migraine and other neurologic symptoms, and so on. This concept is supported by the work of Thorn and others⁴ on water balance studies during the menstrual cycle and the success in treating patients with premenstrual tension by ammonium chloride,⁵ which reduces the amount of sodium retention and extracellular fluid of the tissues.

From the Department of Medicine, Mount Zion Hospital. Supplies of testosterone propionate (Neo-Hombreol) and methyl testosterone (Neo-Hombreol [M]) were furnished by Roche Organon, Inc through the courtesy of Dr. Leo A. Park.

3. Greenhill, J. P., and Freed, S. C.: *The Electrolyte Therapy of Premenstrual Distress*, J. A. M. A. 117: 504 (Aug. 16) 1941.

4. Thorn, G. W., Nelson, K. R., and Thorn, D. W.: *A Study of the Mechanism of Edema Associated with Menstruation*, Endocrinology 22: 155 (Feb.) 1938.

In my experience about 40 per cent of normal menstruating women suffer a considerable amount of distress during their premenstrual period. The disability of most of these women during this period is moderate and obviously affects chiefly their intimate social contacts. Nevertheless the subjective disturbances undoubtedly lead to inefficiency and a decrease in ability to concentrate. As the premenstrual distress averages about five days each month, it becomes apparent that there may be a huge economic loss when these relatively minor errors are summated.

The disharmony in social relationships during the premenstrual period of suffering women is another factor of great importance. This feature is often brought forward by patients who admit that they are "difficult to live with" during this phase. It has been observed that the cyclic distress of these women may intensify social difficulties and frequently perpetuate antagonisms which might lead to drastic action such as divorce, when otherwise there would be a satisfactory adjustment.

The alleviation of premenstrual distress or tension is therefore considered of sufficient importance from the standpoint of health, society and economics to warrant a therapeutic study in order to arrive at an effective and convenient method for the relief of the large number of women who undergo this disturbance. Ammonium chloride therapy has proved quite satisfactory, but it is rather inconvenient. Recently some success has been reported with the use of androgens,⁵ and it appears likely that this type of therapy might prove more satisfactory.

METHODS AND RESULTS

The women selected for study were from my private practice. Six of the 60 total patients were referred primarily for the treatment of premenstrual tension, usually by a psychiatrist. The others were found to suffer from significant degrees of distress, on questioning during their visits for various other reasons. Only those were chosen for study who admitted that they would be highly gratified to obtain relief during this phase, and none were included who stated that though they were uncomfortable they could tolerate the unpleasantness without too much trouble.

TABLE 1.—Treatment of Premenstrual Distress with Testosterone Propionate

Number of Patients	Number of Treatments	Severity of Symptoms	
		Before Treatment	After Treatment
12	18	++	3 + 15 0
13	25	+++	2 ++ 5 + 18 0
6	13	++++	1 +++++ 2 ++ 1 + 9 0

Thirty patients received injections of testosterone propionate on the tenth and third days preceding the expected menses. The amounts of this androgen administered depended on the severity of the symptoms, the dosages being either 10 or 25 mg. at each injection. The results of this treatment are shown in table 1. The severity of the symptoms is designated by the num-

ber of plus marks, the most extreme being 4 plus, graduating down to 0 or absence of symptoms. The relief of the patients is demonstrated so that the residual symptoms are shown by the number of plus signs in a similar manner. Many patients received therapy for more than one menstrual period, as shown in the table.

TABLE 2.—Treatment of Premenstrual Distress with Methyl Testosterone

Number of Patients	Number of Treatments	Severity of Symptoms	
		Before Treatment	After Treatment
10	15	++	1 + 14 0
16	22	+++	6 + 16 0
4	7	++++	1 +++++ 3 + 3 0

It is apparent that most patients obtained definite relief following this treatment. It is only, however, by intimate contact with the patient that the doctor can really appreciate the gratification of the patients for this relief, which in many cases is quite dramatic. Occasionally the injections of testosterone propionate resulted in delayed menses, but otherwise no untoward effects were encountered.

In the second group of 30 patients the oral androgen methyl testosterone was administered in doses of 10 mg. daily, starting ten to seven days before the expected onset of menses. Table 2 indicates the results with this therapy in the same manner as in table 1.

It will be observed from this table that the oral androgen is likewise effective in combating premenstrual distress and tension, perhaps more so than with the injected material. It is my impression that patients were even more gratified with the oral therapy than with the parenteral. In only 1 case was there an untoward reaction following administration of methyl testosterone, and this consisted of nausea.

COMMENT

It is admitted that practically any therapy will relieve a certain number of women of their premenstrual distress through the power of suggestion. Anything which elevates the threshold to psychic stimuli will probably eliminate much of the suffering of these women during the premenstrual phase. Nevertheless a majority of cases do not respond to mild psychotherapy alone, and most patients will report a return of symptoms when specific therapy has been omitted. It has also been observed that when the timing of the menses has been faulty the therapy has proved ineffective, which again indicates that the psychic factor may be of relatively minor importance.

There is some controversy regarding the etiology of premenstrual distress or tension. For a number of reasons it would appear that the increased secretion by the ovaries of estrogen during the premenstrual phase is the responsible factor. Nevertheless, Gillman⁶ claims to have induced similar symptoms by administering large doses of progesterone. On the other hand, Israel² reported that progesterone produced relief of premenstrual tension. In view of the fact that both progesterone and androgens have been shown by a

5. Greenblatt, R. B.: Syndrome of Major Menstrual Mollimina with Hypermenorrhea Alleviated by Testosterone Propionate, J. A. M. A. 115: 120 (July 13) 1940.

6. Gillman, J.: Nature of Subjective Reactions Evoked in Women by Progesterone, with Special Reference to Problem of Premenstrual Tension, J. Clin. Endocrinol. 2: 157 (March) 1942.

number of workers to be effective in combating premenstrual distress and that these substances may be classed as antagonists to estrogen, it seems highly probable that the symptoms are the result of high tissue levels of estrogen during the premenstrual phase. This is further supported by the evidence submitted by Biskind and his associates,⁷ who maintained that premenstrual tension is encountered in patients who have a vitamin B deficiency. This deficiency leads to impairment of the liver to destroy estrogen, with the resulting high level of estrogen circulating in the blood stream and the administration of vitamin B is followed by relief of symptoms coincident with the increased destruction of estrogen of the liver. Furthermore, it may be considered that some of the so-called toxic symptoms induced by certain rapidly absorbed estrogens such as diethylstilbestrol are similar in character to premenstrual distress, that is, headache, nervousness, nausea, bloating and the like. It would appear, therefore, that androgens are effective in relieving the premenstrual distress by neutralizing the endogenous ovarian estrogens sufficiently to prevent the electrolytic changes which give rise to the symptoms.

It is well worth the physician's time and effort to question each menstruating woman regarding any symptoms arising in the premenstrual phase and relieved with the onset of menses, and to administer the appropriate therapy. The patients are most grateful for their relief. They are able to work more efficiently during this time, and in a number of instances social difficulties have been resolved sufficiently so as to prevent serious breaches. Since premenstrual distress is so widespread, immense benefit may be derived from concerted effort to give relief.

Premenstrual distress can be relieved by a number of methods aimed at different elements of the disturbance: (1) progesterone and androgen, the neutralization of estrogen; (2) vitamin B, permitting the normal destruction of estrogen, and (3) ammonium chloride, reducing the sodium retention produced by estrogen. Except for those patients showing signs of vitamin B deficiency, it is my impression that both ammonium chloride and androgen are the most effective and dependable. Parenteral androgen, however, requires relatively frequent visits to the physician. Ammonium chloride must be administered several times daily for two weeks preceding the onset of menses and in varying doses, requiring greater cooperation from the patient than with androgens. It would appear, therefore, that methyl testosterone administered once daily for from ten to seven days before the onset of menses is the surest and most convenient therapeutic agent for the relief of this condition.

SUMMARY

1. Premenstrual tension and distress is a widespread condition occurring in about 40 per cent of menstruating women.
2. Relief of this condition is greatly beneficial from the standpoint of health, society and economics.
3. Both parenteral and oral androgens afford satisfactory relief of this condition.
4. Oral androgen, methyl testosterone, is the surest and most convenient therapeutic agent in this respect.

According to the recent mortality records the majority of deaths from pertussis occur in infants. Between 1938 and 1940 inclusive almost 67 per cent of the 10,730 deaths from whooping cough reported in the United States occurred during the first year of life and 47 per cent of these deaths were in infants under 7 months of age (table 1 and fig. 1). The exceptionally high mortality which pertussis exacts in the first half

year of life calls for thorough investigation of the possibility of increasing the resistance of young infants to the disease by immunizing them shortly after birth. This procedure has been objected to chiefly because of the belief that young infants do not possess the ability to develop active immunity. No extensive study has been carried out, however, to establish the earliest age at which immunity to pertussis can be acquired. Sauer¹ recommends immunization after the seventh month of life on the basis of his finding that only 27 per cent of 89 infants developed complement fixing antibodies following immunization with Hemophilus pertussis vaccine given at or below the age of 3 months, whereas over 70 per cent of the infants inoculated at an older age showed positive complement fixation tests. In Sauer's study pertussis occurred seven times more frequently among children inoculated before the third month of life than among those inoculated after the seventh month. However, he did present evidence to indicate that immunization of infants under 3 months of age was of value, since the attack rate in the immunized group

Presented with permission of the Surgeon General, U. S. P. H. S. Drs. C. E. Roach and W. A. Jamieson of Eli Lilly and Company gave helpful criticisms and supplied materials.

From the Department of Pediatrics, Louisiana State University School of Medicine, and the Louisiana State Department of Health.

Read before the Section on Pediatrics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

1. Sauer, L. W.: The Age Factor in Active Immunization Against Whooping Cough, Am. J. Path. 17: 719-723 (Sept.) 1941.

were classified as mild, moderate and severe, depending on whether their diameters were less than 2.5 cm, between 2.5 and 5 cm, or more than 5 cm, respectively. The fourth category included reactions in which abscess formation occurred. Group B was simply classified as to reactions with or without abscess formation.

The data in table 3 show that 568, or 86 per cent, of the 6,600 inoculations administered to group A resulted in appreciable reactions, but only 48, or 8.5 per cent, of these reactions exceeded a moderate degree of severity. Reactions to more than one of the series of three inoculations were exceptional. Forty-nine

(table 4, group A) developed angioneurotic edema of the eyelids and lips associated with anuria of six hours' duration. Two cases of vomiting, diarrhea and convulsions occurred among infants in group B. In 8 infants transient urticarial or miliarial rashes were observed. Following inoculation an occasional infant developed a paroxysmal pertussis-like cough which disappeared in a short time. Slight irritability and disturbed sleep were also reported with appreciable frequency, but since these extremely mild symptoms were very vague they were not classed as caused by pertussis immunization.

patients reacted to two inoculations and 6 patients reacted with each inoculation.

In group B 39, or 5.5 per cent, of the 703 inoculations resulted in appreciable reactions; 23, or 3.3 per cent, led to abscess formation.

SYSTEMIC REACTIONS TO ALUM PRECIPITATED PERTUSSIS VACCINE

Systemic reactions were classed as mild, moderate or severe, depending on whether symptoms persisted less than twenty-four hours and/or were accompanied by a low fever, lasted one to two days and/or moderate fever, or a high fever lasting more than two days, respectively. Unusual constitutional symptoms occurring in 3 infants were also classed as severe. One patient

Systemic reactions followed 467, or 7.1 per cent, of the 6,600 inoculations received by the members of group A (table 4), but only 16, or 3.4 per cent, of these reactions were classed as severe in character. Thirty-one patients reacted to each of 2 inoculations and 6 infants reacted to each inoculation they received. In group B (table 4) 107, or 15.2 per cent, of the 703 inoculations were followed by reactions, of which only 3, or 2.8 per cent, were classed as severe.

The incidence of local and systemic reactions by color is given in table 5. Local reactions occurred with about equal frequency in the two colors, but there is an apparent significant difference in the incidence of systemic reactions, being higher in the white than in the Negro infants.

CORRELATION OF LOCAL AND SYSTEMIC REACTIONS

The local and systemic reactions are correlated in table 6. The table shows that the occurrence of a local reaction was not necessarily associated with a systemic reaction. Two thirds of the systemic reactions accompanied local reactions and slightly over half (54 per

TABLE 6.—*Correlation of Local and Systemic Reactions, Group A*

	None	Mild	Moderate	Severe	Abscess	Total Local Reactions	Total Observed
None.....	5,872	196	36	1	28	261	6,131
Mild.....	153	151	46	5	8	210	363
Moderate.....	6	62	15	3	2	82	88

Total observed	6,632	420	100	10	38	568	6,600

cent) of the local reactions were associated with systemic reactions. Of the 10 severe local reactions, 6 (60 per cent) were associated with mild or no systemic reaction and only 1 with a severe systemic reaction. Of the 16 severe systemic reactions, 12 (75 per cent) were associated with mild or no local reactions and only 1 with a severe local reaction. Of the 38 abscesses, 28 (74 per cent) were associated with no systemic reaction and 8 (21 per cent) with mild systemic reaction. Not one was accompanied by a severe systemic reaction.

RAPID SLIDE AGGLUTINATION TESTS

Rapid slide agglutination tests were performed on 1,642 Negro and 192 white infants in group A and on 138 infants in group B (table 7) one to four months after completion of the series of inoculations. The table shows that 78.2 per cent of the 1,834 infants in group A gave moderate or strongly positive agglutination tests two to four months after completion of immunization. Of the 138 infants in group B, 112 (81.2 per cent) gave moderate or strongly positive agglutination tests. The discrepancy in the ratio of moderate to strongly positive in the two groups may be due to personal elements involved in interpretation.

TABLE 7.—*The Results of Rapid Slide Agglutination Tests After Completion of the Series of Inoculations*

Type of Reaction	Group A (2-4 Mos. after Last Inoculation)		Group B (1 Mo. after Last Inoculation)	
	Number	% of Total	Number	% of Total
Strongly positive.....	686	37.4	87	63.1
Moderately positive.....	749	40.8	25	18.1
Negative or doubtful.....	399	21.8	26	18.8
Total.....	1,834	100.0	138	100.0

Rapid slide agglutination tests were repeated in 500 of the Negro infants in group A at monthly intervals following immunization, with the results shown in table 8. The data indicate that the greatest number of infants develop positive agglutination tests three to four months following completion of immunization (75 per cent) and that most of these infants (63 per cent) maintain these positive agglutination titers for at least two years.

COMPARISON OF RAPID SLIDE AGGLUTINATION TEST (QUALITATIVE) AND MACROSCOPIC AGGLUTINATION TEST (QUANTITATIVE)

Rapid slide agglutination tests were compared with the macroscopic agglutination tests in 300 subjects. The results may be summarized as follows: In general, those on whom the rapid test was negative or doubtful were found to have titers of 0 to 1:160 in the macroscopic agglutination test; moderately positive rapid test, 1:160 to 1:640; strongly positive rapid test, 1:640 to 1:5,120.

FOLLOW-UP STUDY

A total of 1,834 infants in group A (1,642 Negro, 192 white) and 1,965 nonimmunized infants were closely followed for twelve to twenty-seven months. The rapid slide agglutination tests were performed two to four months after completion of immunization and prior to exposure. The results are summarized in table 9.

SUMMARY AND COMMENT

It has been well established that Hemophilus pertussis vaccine is of value in the modification and prevention of whooping cough. Bell² demonstrated the value of alum precipitated vaccine given in two doses representing a total of 20 billion organisms. Similar results have

been obtained by Kendrick.⁵ The present study was not planned to evaluate a particular vaccine, nor was it intended as a well controlled study of the prophylactic value of the material. It was primarily intended to study (1) the reaction of young infants 3 months of age or younger to parenteral injection of the alum precipitated vaccine and (2) the antibody response, as measured by agglutination tests, of these young infants so inoculated. Data were collected which show that young infants tolerated the inoculations extremely well; 568 (8.6 per cent) of the 6,600 injections in group A were followed by local reactions, 38 (0.6 per cent) by abscesses. Of the 703 injections in group B, 39 (5.5 per cent) were followed by local reactions, 23 (3.3 per cent) by abscesses. These abscesses were all sterile and usually were not associated with a febrile reaction or discomfort; all of them drained spontaneously or disappeared in one or two months. Not one was incised. Very rarely did their presence occasion alarm in the parents. In fact, the abscesses were usually discovered by us. The vast majority of local reactions in group A were mild (74 per cent), characterized by local redness and induration up to 2.5 cm. in diameter. Only 10 (1.8 per cent) were severe, characterized by induration and redness greater than 5 cm. in diameter.

5. Kendrick, Pearl L.: Use of Alum Treated Pertussis Vaccine and of Alum Precipitated Combined Pertussis Vaccine and Diphtheria Toxoid for Active Immunization, *Am. J. Pub. Health* 32: 615-626 (June) 1942.

Local reactions occurred much more frequently following the second and third injections than following the first. There was no appreciable difference in the rate of occurrence of local reactions between white and Negro infants. It was incidentally observed that these young infants tolerated the inoculations much better than did older infants and children, although no attempt has been made in this study to compare the reactions in different age groups.

Systemic reactions were reported following 467 (7.1 per cent) of the 6,600 inoculations in group A. Of this total 16 (3.4 per cent) were classified as severe and 363 (77.5 per cent) as mild. Of the 703 injections in group B 107 (5.2 per cent) were followed by systemic reactions. Of these 3 (2.8 per cent) were classified

as severe and 88 (82.2 per cent) as mild. The criteria used in the classification of systemic reactions were (1) the presence of fever, the degree and duration of which determined the class of reaction, and (2) other constitutional symptoms which were not invariably present. There were 3 instances of quite severe illness following inoculation. These are counted as reactions, though it would be difficult to prove a causal relationship.

A peculiar paroxysmal cough resembling that of pertussis occurred with sufficient frequency to be noted here as related to the inoculation. It began shortly after injection and disappeared rapidly.

Data on the immunologic response of these young infants as measured by agglutination tests also were collected. It is appreciated that the agglutination test with *Hemophilus pertussis* is not an absolute measure of immunity. However, it is accepted as an indication

of immunologic response. The Rapid Agglutination Test (Lilly), a qualitative test, was used throughout the study. The reliability of this test was checked in 300 cases against the macroscopic agglutination test of Miller and Silverberg.⁴ The correlation between the two was remarkable. It is our opinion that the so-called "weak positive" reaction described by Powell and Jamieson³ would more accurately be referred to as "moderately positive" and the doubtful reactions are best considered as negative. Also we concur in the finding that the reaction following vigorous mixing of the antigen with the blood and the delayed reaction after one minute are unreliable.

The greatest proportion of positive reactions was found between the third and the fourth month after completion of the series of inoculations. The effect apparently is a lasting one, since 63 per cent of the individuals tested twenty-four months after completion gave positive reactions. The fact that 75 per cent of these very young infants exhibited antibody response as measured by the agglutination tests used is evidence of the value of immunization early in infancy. This is contrary to the popular belief that young infants are unable to elaborate antibodies following active immunization, and the question of early immunization against pertussis should be reopened for consideration by the profession.

While it was not intended to conduct a well controlled study of the incidence of the disease following immunization, some attempt was made to follow the infants subsequent to immunization. The incidence in those followed who had known exposure, familial or casual, was compared to that in a similar group of nonimmunized urban clinic patients. The results of these observations, though small in number, further suggest that early protection against whooping cough is practicable.

NOTE.—Since this article was submitted for publication, a personal communication from Sauer stimulated us to make a study of the factors which influence abscess formation. Our findings on the basis of over 6,000 inoculations are as follows:

1. Directing the needle downward as recommended by Sauer or upward as usually done did not influence the incidence of abscess formation.

2. Deep subcutaneous or intramuscular inoculations gave a much lower incidence of abscess formation than superficial inoculations.

3. The greatest factor in abscess formation was found to be the intracutaneous introduction of the alum precipitated vaccine. The physician or nurse after transferring the vaccine into a syringe customarily evacuates the air from the syringe and in so doing covers the outside of the needle with the vaccine. This vaccine, which is introduced into the skin during inoculation, sets up an acute inflammation of the skin which soon involves the subcutaneous tissues and leads to abscess formation. The physicians are therefore advised to use a separate needle for injection. In clinic practice it has been found most convenient to leave one needle in the vaccine bottle to transfer the material and to attach a separate dry sterile needle for each inoculation. Since this procedure has been followed, more than a thousand inoculations have been given without a single abscess forming.

ABSTRACT OF DISCUSSION

DR. LOUIS W. SAUER, Evanston, Ill.: United States vital statistics show a sharply accelerated decrease in pertussis morbidity and mortality. Ten years ago the average was 300,000 cases with 6,000 deaths (50 cases to a death); in 1942, 191,383 cases with 2,536 deaths (75 cases to a death). Seventy per cent of 1942 deaths were during the first year of life, three fourths of these during the first seven months, i. e. before the age recommended for pertussis immunization. What remains of the pertussis problem is to prevent pertussis during the early part of the first year of life. The excellent results reported by Drs. Sako, Treuting, Witt and Nichamin augur well. I recommended the four week or monthly interval between the three doses of vaccine several years ago because the same total dose yielded a higher antibody response than did the weekly interval. The authors preferred the four month interval between the last dose and the rapid slide agglutination test, yet in table 6, group B, there were 63 per cent strongly positive tests at one month, and only 37 per cent strongly positive in group A four months later. They attribute this difference to "personal elements in interpretation." I tried out the method as Daughtry-Denmark had suggested (at six weeks) in several hundred infants. I too found some difficulty in interpreting results. I prefer the 3+ and the 4+ complement fixation test as an index of pertussis immunity in investigative work. The authors' observation period for the follow-up study was twenty-six months, probably an average of about one year per infant. Nineteen per cent of 141 injected Negro children and 16.7 per cent of 18 injected white children have already developed pertussis. However, the gratifying and indisputable evidence of amelioration is that no death occurred in the vaccinated, with thirteen deaths among the nonvaccinated (controls). I found it difficult to confer prolonged protection against whooping cough (also against diphtheria) in infants injected during early life. Only 3 per cent of mine injected with plain vaccine, 8 per cent of those injected intracutaneously and 16 per cent of alum precipitated injections showed adequate protection (3+ or 4+ complement fixation). In infants over 7 months old 76 per cent of those injected with plain vaccine and 88 per cent of those injected with an alum precipitated vaccine showed adequate antibodies. Mixed diphtheria toxoid and pertussis vaccine ("combined" immunization) has gained in favor rapidly. Three injections, a month apart, protect against the two diseases simultaneously. Schick still recommends the ninth month as the optimum age for prolonged diphtheria immunization. Mixed diphtheria and pertussis antigens should not be given, therefore, as early as recommended by Drs. Sako, Treuting, Witt and Nichamin. Nothing is known as yet on the duration of immunity conferred so early in life. If more transient, pertussis revaccination might be done later, perhaps at nine months, by three injections monthly of mixed diphtheria toxoid and pertussis vaccine. Already a routine "stimulating" dose of diphtheria toxoid at school age or earlier is obligatory in some cities. Before a radical change in immunization procedure is undertaken, it should be borne in mind that the young infant who develops whooping cough usually contracts it from an unprotected older sibling. Although the most pertussis deaths occur during the first year, the disease is far more prevalent during early childhood. During the first months some infants are feeding problems, others are prematurely born. Local reactions to alum precipitated antigens may be severe. The authors reported occasional abscesses. Severe local reactions in private practice and in municipal clinics have deterred many physicians from using any alum precipitated antigens. Miller and others recommend agents less irritating than alum. Pertussis vaccine should be injected at the earliest age at which adequate immunity can be conferred.

DR. WALLACE S. SAKO, New Orleans: The difference in the interpretation of the moderately and strongly positive reactions I attributed to personal elements because in several instances it was difficult to draw a dividing line between the two reactions. When it comes to taking the two reactions together and adding them, in one group the positive reaction occurred in 78 per cent and in the other group in 82 per cent. We do not

contend that the agglutination test is an absolute measure of immunity. However, it is generally accepted as a measure of immunologic response. Regardless of the agglutination test or the complement fixation test in these young immunized infants, the fact remains that the disease when contracted is milder and the mortality is lowered. In both Dr. Sauer's series and in ours the significant thing is that there were no deaths in the immunized group, and the disease when contracted was mild. Abscesses occurred in a small number of infants, but they occasioned no alarm. The majority of them gave no systemic reactions whatever. The routine immunization of young infants, therefore, is recommended because of the low incidence of both local and systemic reactions. Although the few local abscesses which may occur might occasion some objection from the parents in private practice, it is significant that none of our parents discontinued immunization because of them. The state of Louisiana since 1942 has adopted the immunization routine outlined as a regular program in the well baby clinics conducted throughout the state. To date more than 16,000 infants below the age of 2 months have been so immunized. It is significant also that the mortality figures for the state of Louisiana since 1942 showed no deaths reported from the immunized group. This study was conducted as a joint project between the Louisiana State University School of Medicine and the Louisiana State Department of Health.

SIGNS AND SYMPTOMS OF IMPENDING CEREBRAL HEMORRHAGE

R. D. TAYLOR, M.D.

AND

IRVINE H. PAGE, M.D.

INDIANAPOLIS

Symptoms referable to the nervous system which precede the onset of cerebral hemorrhage and the association of apoplexy with necropsy evidence of left ventricular hypertrophy have been recognized since the times of Galen and Morgagni.¹ Lidell² in 1873 described in detail transient paresthesia, aphasia, temporary motor paralysis, vertigo and syncope, memory defects and blind spots, as frequent prodromes of fatal apoplexy. When arterial hypertension was recognized, it soon became apparent that the vast majority of such accidents were due to this disease (Lippman³ and Baer⁴), and most contemporary discussions of essential hypertension⁵ mention that signs and symptoms of impaired cerebral circulation can be the forerunners of cerebral hemorrhage. However, possibly because they have been erroneously considered to be manifestations of the comparatively benign hypertensive encephalopathy described by Fishberg and Oppenheimer,⁶ the value of these findings seems to have been generally lost sight of, so that there is at present no accurate method of predicting which patient with essential hypertension is likely to have a stroke. Such a means of prognostic selection might be of value in protecting those apt to

die of apoplexy, and, what is more important, it would offer assurance and comfort to those who probably will not.

The present communication is an analysis of the records of patients who died with, or of, essential hypertension, in which an attempt is made to determine whether or not there are enough points of similarity among those who had cerebral hemorrhage to define an antecedent syndrome that segregates this group (group H) of patients from other patients with essential hypertension (group C).

METHODS OF STUDY

Selection of Cases.—Forty patients who died of essential hypertension were studied in the past three years. The diagnosis of essential hypertension was established by demonstrating arterial hypertension, electrocardiographic or teleoroentgenographic evidence of hypertensive heart disease, renal hemodynamic changes consistent with essential hypertension and the presence of hypertensive retinopathy. The retinopathy included constriction and sclerosis of the retinal arterioles and retinal hemorrhages in the absence of papilledema and exudates. When either or both of the last two findings were present, the disease was considered malignant (Keith, Wagener and Kernohan⁷) and was excluded from this series. Also excluded was that group who showed no evidence of advancing blood vessel disease or renal changes consistent with essential hypertension and have been designated elsewhere as "neurogenic" (Corcoran, Taylor, Shrader, Young and Page⁸).

METHOD OF GRADING RETINOPATHY

Each component of the hypertensive retinopathy was graded on a 1 to 4 basis. Grade 1 constriction was recorded when, in the absence of sclerosis, the diameter ratio of arteriole to venule (arteriovenous ratio) was at all reduced below the normal 4 to 5, or, when slight, local vasospasm was visible. Grade 2 constriction indicated a reduction of the vessel size ratio to 3 to 5, or definite sausage-like, segmental vasospasm and straightening of the graceful curves of the normal retinal arterioles. Grade 3 constriction was thought to be present if, in addition to the foregoing findings, the arterioles were so constricted and shortened that they seemed not to extend into the periphery of the fundus. The small distal arteriolar segments were not visible. Grade 4 was reserved for those vessels that seemed to be straight reddish lines coursing through the retina and whose size relation to the veins was 2 to 5 or less. Such severe constriction, in the absence of sclerosis, probably rarely occurs in essential hypertension; however, when present, it can account for slight venous compression.

Beginning or grade 1 sclerosis indicated visible "hardening" of the rich, soft, plushlike red color of normal retinal arterioles. The velvety coat that seems to surround healthy vessels was gone. Grade 2 described the presence of early perivascular reaction as evidenced by fuzzy, dull, red areas along the arterioles. At this stage the retinal veins occasionally showed slight compression as they passed under arterioles. Grade 3 sclerosis was thought to be present if the arteriovenous ratio was reduced to 3 to 5 and the retina immediately

adjacent to the arterioles was of a hard, whitish appearance. Grade 4 was reached when the retinal veins were severely compressed as they passed under arterioles and the arterioles themselves were reduced in size to a 1 to 2 arteriovenous ratio. The adjacent retina seems to sheath them like stockings. The light reflex from these vessels has been compared to a silver wire.

The gradation of retinal hemorrhages represented the sum of such lesions in both eyes. Grade 1 indicated the presence of one to three hemorrhages, grade 2 four to six hemorrhages, grade 3 six to ten hemorrhages and grade 4 more than ten. In some fundi, whitish areas were present that somewhat resembled the exudates of malignant retinopathy. However, these white areas were harder and more sharply demarcated. Over a period of months one could occasionally observe such lesions develop as hemorrhagic exudate was absorbed. Five cases in this series gave such findings.

METHODS OF COLLECTING CLINICAL DATA

The average blood pressures obtained from weekly averages of twice daily readings taken during bed rest were recorded. The duration of hypertension was estimated, as with all patients in this clinic, from previous blood pressure measurements. Employers, insurance companies, hospitals, schools and physicians have all been cooperative in providing these values; thus in most cases the beginnings of the disease could be dated. The onset of symptoms heralding the mode of death was dated, retrospectively, from the first sign suggesting the ultimate fatal illness.

The clinical signs and symptoms considered dealt only with evidence of damaged cerebral circulation or of hemorrhagic tendencies, such as nosebleed, and gastrointestinal hemorrhage. Evidences of concurrent disease of the heart or kidneys were disregarded except as they delimited the nature of the hypertensive state.

All complaints were graded on a 1 to 4 basis, where grade 1 indicates the mere presence of a symptom and grade 4 constant or incapacitating proportions. The symptoms ascribed to abnormal cerebral circulation were headache, vertigo, syncope, paresthesia, temporary paralysis or paresis, aphasia, amnesia or visual disturbances.

The type and location of headaches were given special attention. Vertigo was recorded only when the world seemed to turn about the patient. Simple dizziness and lightheadedness were not considered. Syncope included temporary "blackouts" and complete loss of consciousness. Paresthesia was used to indicate all abnormal sensations from numbness and tingling of any part of the body to areas of complete anesthesia. Transient paralyzes ran the gamut from weakness of a limb or finger to hemiplegia lasting twelve to thirty-six hours. Motor aphasia and oculomotor disturbances were also listed under this heading.

The cause of death was established by postmortem examination in 18 of 40 cases, by clinical observation and the demonstration of grossly bloody spinal fluid in 9 others, by surgical exploration in 1 and by unequivocal clinical and laboratory findings in the remaining 12.

RESULTS

Cause of Death.—Among the 40 patients with essential hypertension 19, or 47.5 per cent, died of cerebral hemorrhage; 10, or 25 per cent, of congestive heart failure; 4, or 10 per cent, of coronary occlusion with myocardial infarction; 2, or 5 per cent, of renal failure. The remaining 5 patients (12.5 per cent) died of causes

other than hypertension, namely carcinoma of the pancreas, pulmonary tuberculosis with Addison's disease, tuberculous peritonitis, dissecting aortic aneurysm and an undetermined cause (tables 1 and 2).

The average age in group H (for hemorrhage) was 46.8 years and 50.3 years in the other.

Duration of Hypertension.—The duration of hypertension was established as accurately as possible by exploring every source for earlier blood pressure measurements. The courses of those who died of cerebral hemorrhage were shorter than those of the others. The

on a 1 to 4 basis, while the mean of the others was less than one half this, or 1.1. Only 1 patient who died of causes other than cerebral hemorrhage had nuchal headache of more than grade 1 severity (patient S. L., table 4). The cause of her death could not be established at autopsy, but there was reason to believe that it may have been barbiturate poisoning.

Vertigo and Syncope.—One or both of these symptoms were present in 18 of 19 patients with cerebral hemorrhage, and the average severity was 2.3. Only 4 of the other group offered this as a complaint. In

mean duration of group H was 7.0 years (range 4 to 12.5) and, of the other, 9.0 years (range 4 to 19) (tables 1 and 2).

SIGNS AND SYMPTOMS PRECEDING DEATH

Headache.—These observations are summarized in tables 3 and 4. Although headache was only slightly more common among those who died of cerebral hemorrhage (18 of 19 as compared to 16 of 21), the type of headache and the severity showed wide differences. Twelve of those who developed apoplexy previously complained of nuchal and occipital pain, without headache in other regions, while only 5 of the controls mentioned distress of this type. Further, the severity of headache in group H had a mean severity grade of 2.5

3 of these it was of a grade 1 variety, while the fourth complained of grade 2 vertigo. She again is the S. L. referred to in the preceding paragraph.

Paresthesias or Transient Paralysis, Aphasia, Convulsive Seizures.—At some time during their illness, 17 of the 19 persons who eventually had apoplexy gave evidence of temporary cerebral circulatory insufficiency. These complaints ranged from recurrent numbness and tingling of the fingers or face to convulsive seizures and hemiplegia lasting two to thirty-six hours. Other variations of this group of symptoms were diplopia of three days' duration following an attack of ataxia, temporary and permanent loss of a quadrant or entire visual field, transient aphasia and amnesia, and permanent muscle weakness or sensory defect which were attributed to

small thrombi. One or more of these manifestations were noted alternately on the left or right side or bilaterally by 10 of those 17 patients who had neurologic symptoms. Five experienced right sided disturbances, while in 2 cases the left side of the body was involved. This lateralization had no relation to the cerebral hemisphere involved in the fatal attack (table 5). The mean severity grade of these findings was 2.0, where grade 1 indicates the presence of a symptom and grade 4 incapacitating proportions. The duration of life from the appearance of the first neurologic sign averaged 1.5 years (0.25 to five years), six months shorter than the mean span of life dated from any other complaint common to group H.

In sharp contrast to this picture, but 2 of the 21 patients in the other group even mentioned numbness, and this amounted to very slight tingling of one or two fingers, occurring but once in each.

Nosebleed.—The difference between the two groups as regards hemorrhage from the nose was less evident. Nine of those who died of cerebral hemorrhage reported

nosebleeds. Five of the 21 other patients experienced nosebleeds. These were comparatively less frequent and severe.

Arterial Blood Pressure.—The arterial blood pressures of those patients who had strokes were only slightly higher than those in group C. The mean of the blood pressures in group H was 210/124 mm. of mercury (the range was 180/100 to 260/140 mm. of mercury) and the mean of group C 196/117, with a range of 160/106 to 250/150.

Optic Fundi and Retinal Arterioles (tables 1, 2, 3 and 4).—The examination of the optic fundi aided in segregating those who later developed apoplexy. The degree of constriction and sclerosis of the retinal arterioles was greater among those patients. The vasoconstriction had a mean grade of 2.6 (range 2 to 4) and arteriosclerosis a mean of 2.4 (range 2 to 4) as compared to the patients of group C, in whom both constriction and sclerosis averaged 1.9 (range 1 to 3). These differences, apparent in average values, overlapped in individual cases so as not to aid in prognosis.

The important factor of fundoscopic differentiation lay in the observation of retinal hemorrhages. All but 3 of the 19 subjects with cerebral hemorrhage

(group H) had retinal hemorrhages or scars of old hemorrhages, while only 2 of the other group developed these lesions, and in 1 of these, E. T., tables 2 and 4, the hemorrhages were of the large subretinal type often seen in patients with senile changes in the retina. The hemorrhages that were seen were usually few in num-

ber, with a mean grade of 1.41, or approximately two hemorrhages in each eye. When such lesions were in close association with blood vessels, they were smaller, harder and more linear than the soft, flame shaped hemorrhages of malignant hypertensive retinopathy. In addition to this type of hemorrhage, a droplike spot of bleeding was often observed some distance from an arteriole.

death, the earliest suggestion of heart failure, renal failure or other terminal illness was chosen. Among those who died of cerebral hemorrhage the duration of the fatal illness was dated from the appearance of the signs or symptoms we have considered. The 5 patients in group C who died of coronary occlusion and dissecting aneurysm were omitted from the calculation because they gave no sign that might have suggested such an accident.

Those who died of cerebral hemorrhage lived an average of 2.1 years (0.8 to five years) and the others 2.6 years (0.6 to six years) after the first symptom of the ultimate cause of death. The accompanying charts compare the average clinical picture of these two groups of patients.

Chart 1.—Average clinical course in group H.

COMMENT

The tragic abruptness with which cerebral hemorrhage ends the lives of comparatively young persons (average age of this group 46.8 years) led us to a search for methods whereby the event might be anticipated. Studies of the heart and kidney can provide, with satisfying accuracy, estimates of the state of coronary and renal vessels, but there are no present means for comparable analyses of the cerebral circulation, and we are left with clinical findings as the only guides to the integrity of this important vascular bed. Our data indicate that clinical study of individuals with essential hypertension may draw a picture peculiar to those patients who are likely to have apoplexy.

Patients in this series who died of cerebral hemorrhage presented concurrent findings that were uncommon among other essential hypertensives. Exhaustive investigation of individual medical histories indicated that the average length of disease among those who had apoplexy was 20 per cent shorter than those dying of other causes. The presenting complaints almost always included nuchal and occipital headaches, often incapacitating. One or more neurologic signs of impaired cerebral circulation appeared. These were vertigo and syncope, aphasia, memory defects, transient paralyses or paresthesias and visual disturbances. Nosebleeds were also more common.

Physical examination demonstrated slightly higher and more stable levels of arterial blood pressure in those who eventually succumbed to cerebral hemorrhage. In this group the retinal vessels were 30 per cent more severely constricted and sclerosed than in the others. The appearance of three or four linear or drop-like retinal hemorrhages was of special significance. It occurred in all but 3 of those in group H and in only 2 of those whose death was not the result of cerebral hemorrhage, and in 1 of these the hemorrhages were atypical and apparently due to other causes.

Five elements were especially common among those in group H. These were (1) severe nuchal or occipital headache, (2) vertigo or syncope, (3) motor or sensory neurologic disturbance, (4) nosebleed and (5) retinal hemorrhages in the absence of papilledema or exudates.

All but 1 of 19 patients who had apoplexy presented at least four of these five signs and symptoms, and the remaining patient had three of them. Contrariwise, only 3 of the 21 individuals who died of other causes had as many as three such findings, and these were less pronounced. Our patients who had apoplexy lived an average of 2.1 years (range 0.8 to five) after the appearance of any one of these five signs and symptoms. The incidence of cerebral hemorrhage in essen-

Chart 2.—Average clinical course in group C.

tial hypertension, as we define this state, is much greater than the 7.2 per cent of Paullin, Bowcock and Wood⁹ and the 14 per cent of Janeway.¹⁰ This may be because we excluded those with malignant and

"neurogenic" hypertension (Corcoran, Taylor, Shrader, Young and Page⁸), most of whom die of other causes.

If the symptom complex present among this group of patients proves useful in predicting cerebral hemorrhage, it may be that the problem of preventing these accidents has been made an accessible field of study.

SUMMARY AND CONCLUSIONS

The records of 40 patients who died with essential hypertension were examined to determine whether or not the clinical courses of those who died of cerebral hemorrhage were similar enough to allow an accurate prediction of apoplexy. Among this group 19 had fatal cerebral hemorrhages. Five signs and symptoms were consistently observed. These were (1) severe occipital or nuchal headaches, (2) vertigo or syncope, (3) motor or sensory neurologic disturbances, (4) nosebleeds and (5) retinal hemorrhages in the absence of papilledema or exudates. These findings were negligible or absent among those patients who died of other causes. It is concluded that demonstration of any four of these manifestations in persons with essential hypertension warrants the assumption that death from cerebral hemorrhage will occur within 0.8 to five years (average 2.1 years).

SKIN HAZARDS IN THE MANUFACTURE AND PROCESSING OF SYNTHETIC RUBBER

LOUIS SCHWARTZ, M.D.

Medical Director, Chief, Dermatoses Section, Industrial Hygiene Division, Bureau of State Services, U. S. Public Health Service, Federal Security Agency

BETHESDA, MD.

When the war cut off our principal supply of natural rubber from the East Indies it was necessary to find a substitute in order to carry on the war successfully. For more than twelve years before the war the Du Pont de Nemours Company had made neoprene, the first of our synthetic rubbers. Shortly before we entered the war the Standard Oil Company of Louisiana obtained the German patents for making buna S, the type of rubber now mostly used.

The principal types of synthetic rubbers now manufactured in this country are buna S, buna N, butyl rubber and neoprene. Buna S, butyl rubber and neoprene are the types now being made for our armed forces.

BUNA S

Buna S is made from butadiene and styrene. Butadiene can be made from alcohol and from butylene, a product fractionated from high line gas and light pressure distillate taken from petroleum oil.

BUTADIENE FROM ALCOHOL

Ethyl alcohol is heated in closed kettles over a catalyst and converted to acetaldehyde. The acetaldehyde is heated over a catalyst to form butadiene. These processes take place in closed kettles, and there are no exposures of the workers to the chemicals because the operation is controlled from a control room. However, in cleaning the kettles and reactors the maintenance crews come in contact with some of the chemicals formed during the conversion, and cases of dermatitis have occurred chiefly from acetaldehyde. Among the other chemicals and by-products which may

be encountered in cleaning retorts and kettles, the irritants are butylaldehyde methylethyl ketone and acetic acid.

Tertiary butyl catechol is added to the butadiene in order to keep it from polymerizing while in the storage. Tertiary butyl catechol is a skin irritant, and workers opening the cans containing this product may develop dermatitis from splashes if they do not wear rubber gloves and impervious sleeves and aprons.

Butadiene is a volatile gas under ordinary conditions of temperature, and any dermatitis resulting from it is probably due to the freezing effect of its evaporation.

In plants making butadiene from ethyl alcohol, maintenance workers going into kettles, retorts or pipes for cleaning or repairing should wear rubber gloves, goggles, airline respirators or gas masks, impervious coveralls and boots. They should step under the shower with all these clothes on immediately after completing the job in the retorts and then remove the protective clothing and don their street clothes.

While handling tertiary butyl catechol, workers should wear goggles, rubber gauntlets and rubber aprons, which should be kept close by the tank in which the cans are opened and melted.

BUTADIENE FROM BUTYLENE

Butylene is heated to a high temperature in reactors in contact with a catalyst resulting in the formation of butadiene. The entire process is totally enclosed and automatically controlled. Skin hazards are present only to maintenance men cleaning or repairing the reactors. When such work is being performed the men should be protected as prescribed for maintenance men making butadiene from alcohol.

STYRENE MANUFACTURE

Ethylene is combined with benzene in order to form ethylbenzene. Aluminum chloride is used as a catalyst in this operation. The aluminum chloride is dumped into the hopper by hand and the worker is exposed to it twice during a shift. Since aluminum chloride is a skin irritant, the worker while engaged in handling it should wear rubber gauntlets, aprons and goggles. Sodium hydroxide is used in the process. Workers handling the caustic should wear rubber gauntlets, aprons and safety goggles. The waste discharged from the reaction of ethylene with benzene is a black tarry irritant substance. Therefore workers handling this waste should also wear rubber gloves, impervious sleeves and aprons. They should be instructed to change their clothes immediately after they become soiled with this tarry material. Ethylbenzene is heated over a catalyst to form styrene. This process is totally enclosed. Tertiary butyl catechol is added to styrene to prevent polymerization while in storage. While handling this chemical the workers should wear goggles, rubber aprons and gauntlets.

MANUFACTURE OF BUNA S

Buna S is made by stirring a mixture of butadiene, styrene, soap solution, an oxidizing salt and a chain modifier in a polymerization kettle for about eighteen hours. Hydroquinone also is used. The unreacted styrene and butadiene are recovered from the latex. The antioxidant is then added to the latex. The latex is coagulated by adding acidification and the rubber is screened out of the liquor, washed, dried, baled, powdered and packed. The butadiene and styrene are usually brought to the plant in tank cars. Workers engaged in emptying the styrene tank cars should wear

From the Dermatoses Section, Industrial Hygiene Division, Bureau of State Services.

Read before the Rubber Section of the National Safety Council Meeting in Chicago, Oct. 3, 1944.

impervious protective clothing to protect them from accidental splashes. The process of removing tertiary butyl catechol from butadiene by bubbling it through a solution of caustic soda entails no hazard because it is totally enclosed. The red liquid, sodium salt of tertiary butyl catechol, is disposed of by burning.

Most of the occupational dermatitis occurring in the manufacture of buna S is caused by chemicals added to the butadiene and styrene in order to make the reaction possible. These chemicals are as follows: 1. The per salt which is used as an oxidizer or catalyst rarely causes dermatitis. 2. The chain modifier which is added to the mixture in the polymerization kettle is a primary irritant and sensitizer. 3. Hydroquinone, which is added to the latex in the polymerization kettle, is a sensitizer. 4. The antioxidant, usually consisting of phenylbetanaphthylamine, is a sensitizer. Bardol, a coal tar derivative, is sometimes added to the phenylbetanaphthylamine. Bardol is a primary irritant and photosensitizer. 6. Soapstone or talc is used to cover the bales of rubber. Dermatitis can result from coarsely powdered soapstone, especially in hot weather. 7. The compound which is sometimes used as a modifier instead of or in conjunction with the original modifier is also a primary skin irritant. 8. Sodium lignin sulfonate, sometimes used, is a sensitizer.

Workers in the pigment room handling these chemicals should wear protective clothing in the form of rubber gauntlets, impervious sleeves and aprons. Workers dumping chemicals into reaction kettles should wear similar protective clothing.

Workers engaged in handling the baled rubber are exposed to soapstone and talc and often develop dermatitis. The talc and soapstone are usually coarse and contain sharp spicules which wound the skin, especially when it is perspired and macerated. Unless some method is devised whereby the dust exposure to the workers is eliminated, such workers should wear closely woven coveralls and leather gloves, cleaned daily in the plant. They should also be compelled to take shower baths after work. In some plants a very fine grade of talc is used, fine enough to pass through a 300 mesh screen. In such plants there is no dermatitis from talc.

Dermatitis also occurs among workers making the coagulating solution. In warm weather this solution deposited on the perspiring skin of the arms can cause dermatitis. Protective sleeves will prevent this condition.

Workers engaged in making the soap solution may also develop dermatitis from the soap flakes. Protective sleeves and aprons will prevent this.

A considerable portion of the dermatitis occurs among the workers engaged in cleaning the driers. They are compelled to enter the driers and lie on their backs in closely confined spaces, removing from the traveling chain or belt the adherent, incompletely polymerized rubber. Dermatitis occurs on the body of these workers and is caused by the incompletely polymerized rubber and the uncombined chemicals which it contains.

About 0.5 per cent of the styrene remains unchanged in the rubber as it comes from the drier. The phenylbetanaphthylamine in the incompletely polymerized rubber combined with the bardol sodium lignin sulfonate, and so on, are probably the principal causes of dermatitis among workers cleaning the driers. The faces of these workers should be protected by a protective ointment of the lanolin-castor oil type. They

should be furnished with clean coveralls and gloves and take compulsory showers after each session in the driers. The future driers should be roomy and so constructed that the workers can clean them in a standing position. Samplers of latex in the reactor building should wear rubber gauntlets, impervious sleeves and aprons while drawing fluid from the reactors. Workers dipping their hands into the slurry of rubber, brine, latex and acid in the coagulation building should wear rubber gauntlets. In some plants soda ash is added to soften the water used in making the soap solution and the brine. Workers coming in contact with soda ash should be furnished with impervious coveralls and rubber gloves, daily cleaned at the plant, and should be compelled to take showers after work.

NEOPRENE

There is comparatively little dermatitis in the manufacture of neoprene. The principal type of neoprene manufactured is called type G. R. M. and is made from acetylene. This is converted into vinyl acetylene by the use of a catalyst. The reaction takes place in retorts placed behind explosion proof walls and is remotely controlled. Vinyl acetylene is a gas with a boiling point of 5 C. Vinyl acetylene is reacted with hydrochloric acid to form chlorobutadiene. Chlorobutadiene is a liquid with a boiling point of 60 C. It is a primary irritant, and accidental splashes cause erythema even if it is soon washed off with water. Chlorobutadiene is mixed with sulfur and rosin placed in a kettle of soap solution to which a per salt is added as a catalyst and is agitated for about two hours to form neoprene latex. In emptying the kettles some of the latex spills on the floor and dermatitis occurs on the feet and legs of operators from contact with the latex. The latex contains unreacted chlorobutadiene, the pungent odor of which is present in the building. The latex has a p_H of 10, which also adds to its irritant properties. About 5 per cent of the workers exposed to chlorobutadiene have some temporary loss of hair. It is not known whether this is caused by a local or a systemic effect. The hair becomes normal after exposure ceases.

The neoprene latex is deposited into cooled revolving drums which coagulate the neoprene and roll it off in a thin sheet. The sheet is washed and then passed festoon fashion through a drier. After coming from the drier it is compressed into roll form, passed through finely ground talc, cut into lengths of about 12 inches and packed into bags. There have been no cases of dermatitis among the workers exposed to the finely ground talc.

Other types of neoprene are type G. N., type I, type K. N. and type F. R. These differ somewhat in composition. Neoprene latex is made from type G. N. and is simply the uncoagulated latex. The latex liquor is made from rosin soap and has a p_H of 9-10. It also contains a small amount of unreacted chlorobutadiene.

BUTYL RUBBER

Butyl rubber is made from isobutylene and isoprene. These chemicals are dissolved in methyl chloride and reacted over a catalyst (aluminum chloride). The liquid is circulated and cooled in a reactor through metal tubes. As the rubber is formed it rises to the top of the reactor, where it meets a stream of steam which carries the rubber away. Phenylbetanaphthylamine is added to the slurry of hot water and rubber. The worker adding the phenylbetanaphthylamine should wear rubber gauntlets, impervious sleeves and aprons. The rubber is screened out of the slurry and then

passed through a drier, from which it is extruded in a continuous sheet. Xylyl mercaptan is added to the rubber before it passes through the extruder. This substance is a skin irritant and the workers at the extruder should wear impervious sleeves and aprons, and a protective ointment on the face. The rubber after coming from the extruder is passed through a hot mill. The workers on the mill develop burns and blisters of the hands from the hot rubber and dermatitis from the fumes of phenylbetanaphthylamine and xylyl mercaptan. They should be provided with heat proof gloves and a protective ointment for the face.

BUNA N

Buna N is made by reacting butadiene with acrylonitrile in a manner similar to that described for the manufacture of buna S. Buna N is partially dehydrated in a centrifuge or by pressing between rollers before being passed through the drier. The temperature of the drier is higher than that for buna S, and the time of drying is less. Practically all the unreacted monomers remaining in buna N are vaporized in the drier and drawn off by suction. The driers are roomier and do not require as frequent cleaning as do the driers for buna S, and the workers entering the drier are not required to lie on their backs and work in narrow spaces. The raw chemicals used in the manufacture of buna N are (1) butadiene, (2) acrylonitrile, (3) soap suds containing a wetting agent, (4) a modifier, (5) a catalyst which consists of oxidizing salts, (6) an antioxidant, which may be phenylbetanaphthylamine or phenylalphanaphthylamine or stalite, (7) sulfuric acid in a concentration of 0.5 to 1 per cent, used to coagulate the latex, (8) a 2 per cent barium chloride solution, which may also be used for this purpose, and (9) bone glue and casein used as emulsifiers.

Dermatitis may occur from acrylonitrile, which may leak out of enclosed pipes and retorts. The soap solution containing a synthetic wetting agent may cause irritation of the nose and throat. The modifiers are primary skin irritants. The antioxidants are sensitizers. Barium chloride may cause a dry scaling eczema of the palms.

The whole operation of making buna N is more enclosed than that for making buna S, and despite the fact that acrylonitrile is a powerful skin irritant there were no cases of dermatitis seen in the buna N plant which was inspected.

PROCESSING SYNTHETIC RUBBERS

The skin hazards occurring in the processing of synthetic rubbers are the same as those described for natural rubber, namely from the chemicals used in the rubber, with the addition of hazards from the synthetic rubber themselves. The chemicals to be used in the rubber are weighed out by hand. The worker comes in contact with all of them and should be protected with rubber gloves, impervious sleeves and aprons and a respirator. The rubber, either synthetic, natural or reclaim, and the chemicals are mixed into master batches, which contain a high percentage of the ingredients. These master batches are the ones used for compounding the actual rubber stock.

The chemicals to go in the rubber are mixed together either in a mixing mill or a Banbury mixer. The workers on the mixing mills come in contact with the chemicals and are exposed to whatever fumes may come off the rubber as it gets hot, and sensitization dermatitis may occur among them. The mix mills should be well exhausted and those workers who become

sensitized and develop dermatitis should be provided with a protective ointment of the water repellent type. Protective clothing is too hot to wear at this operation. Workers on the Banbury should wear clean dustproof coveralls furnished daily by the plant. Workers on the mix mills and the Banbury should take cleansing showers before going home. In most factories the rubber after being compounded is sheeted out and passes overhead in a continuous sheet to the various departments, where it is further processed.

Rubber which is going to be made into tires is extruded in the form of the tread. The fabrics, such as cotton and rayon, going into tires are impregnated with rubber either by calendering or by dipping into water dispersions. These operations are automatic and there are no particular skin hazards connected with them.

Rubber to be made into tubes is extruded through a tube shaped die, cut off into suitable lengths and cemented into circular tubes. Workers engaged in this operation sometimes get dermatitis from the rubber cement, which consists essentially of rubber dissolved in a solvent. Workers at this operation who develop dermatitis should wear thin washable leather gloves and use a long handled brush for applying the cement.

Tire builders handle fabrics impregnated with rubber and the various compounded rubbers which go into the tread and sides of the tire. They rarely develop sensitization dermatitis from the chemicals in the rubber.

The synthetic rubbers can be used in latex form. Thin rubber gloves may be made directly from latex in the same manner in which they are made from natural latex. Dermatitis may occur from synthetic latex because it contains more of the uncombined and unpolymerized chemicals than does the coagulated dried rubber.

PATCH TESTS

Hundreds of patch tests were performed on workers having dermatitis in the twenty plants inspected. Of twenty-four chemicals used as patch tests, the following positive reactions were obtained:

- Phenylbetanaphthylamine, antioxidant.
- Stalite, antioxidant.
- Hydroquinone.
- Buna S from driers.
- Neoprene latex.
- Safex (2, 4 dinitrophenyl dimethyl thiocarbamate), accelerator.
- Captax (mercapto benzo thiazole), accelerator.
- Eric (bis- 4, 5- dimethyl thiazyl disulfide), accelerator.
- Altax (benzothiazole disulfide), accelerator.
- Santocure (benzothiazyl 2, monocyclohexyl sulfonamide), accelerator.
- Asphalt.
- G. R. S.
- Buna N type of synthetic rubber.

SUMMARY

There is comparatively little dermatitis occurring in the manufacture of synthetic rubber despite the many irritant chemicals used. This is explained by the fact that the factories making synthetic rubbers are modernly equipped with mechanical safety devices and most of the safety recommendations made in this paper are already being carried out.

We need to anticipate but little more dermatitis from the manufacture and processing of synthetic rubbers than we have had from natural rubbers, provided future plants are erected with the same careful planning as the present ones and the safety recommendations in this paper are carried out.

COMMON MISTAKES IN HANDLING OF PATIENTS WITH ARTHRITIS AND ALLIED CONDITIONS

BERNARD I. COMROE, M.D.

PHILADELPHIA

Mistakes in the handling of arthritic patients often lead to unnecessary deformities and crippling. In some instances omission of proper therapy delays early recovery.

Some practitioners unfortunately treat arthritic patients for long periods without first establishing a definite diagnosis. Every effort should be made to diagnose the type of arthritis as soon as possible. This does not mean, however, that affected joints should not be splinted or that mild analgesics should not be given during periods of study of the patient. Physicians frequently err on this side and permit contracture deformities to develop and pains to persist because they think only in terms of a diagnosis without considering the patient's pain and discomfort and the progressive development of deformities.

Every patient with joint symptoms should have a complete history, thorough physical examination and appropriate laboratory tests. Rheumatoid arthritis, for example, may be simulated by numerous nonarthritic entities, such as parkinsonism, brucellosis, syphilis, leukemia, Raynaud's syndrome, scleroderma, hypothyroidism, hyperthyroidism and lupus erythematosus. Occasionally it is difficult even after a complete examination to differentiate between such diseases as early rheumatoid arthritis and acute rheumatic fever; this may require the passage of considerable time and follow-up studies.

It is a mistake to depend too much on the sedimentation rate alone in the diagnosis of joint disease. This test should be used only in conjunction with common sense, coupled with a carefully taken history and a thorough physical examination, blood count, urinalysis, serologic test for syphilis and x-ray films of the involved joints.

The sedimentation rate is not infallible and, if the results of this test are not in agreement with the diagnosis, the test should be repeated. If disagreement persists, the diagnosis should be questioned or one should search that patient for the presence of additional pathologic change which may be causing the rapid rate. Physicians occasionally forget that the sedimentation rate may be increased in pregnancy or during menstruation. A rapid sedimentation rate occurs in many disorders, such as sinusitis, bronchitis, pyelitis and osteomyelitis, when no joint phenomena are present.

A normal sedimentation rate does not rule out organic disease. Various forms of joint pathologic conditions may occur in the presence of a normal sedimentation rate, as in degenerative joint disease, most cases of fibrositis, gout (in the interval between acute attacks) and in patients with rheumatoid arthritis whose active process has been burned out and who are left with their deformities and crippling and an inactive process.

It is a mistake to tell the patient that the joint is normal because the x-ray examinations are negative. Despite the absence of obvious x-ray changes, one may have well defined limitation of motion in the joints.

One should not rule out rheumatoid arthritis on the basis of negative roentgenograms; early signs of rheumatoid arthritis may not appear on the roentgenogram for months or years. Similarly, punched-out areas in bones seen by x-ray should not be considered pathognomonic of gout, as they may occur in other disturbances such as rheumatoid arthritis and some cases of degenerative joint disease.

Numerous mistakes are made in the x-ray study of joints. One of the commonest of these is to accept the roentgenologist's report that there is no subdeltoid bursitis merely because he sees no evidence of calcification in the supraspinatus tendon. X-ray evidence of subdeltoid bursitis is present in not more than 50 per cent of cases; negative roentgenograms do not rule out subdeltoid bursitis.

Many conditions may manifest the same basic alterations in the x-ray. The pathologic and x-ray response of joints in various diseases is too similar to permit dogmatic interpretation of the roentgenogram. One should never rule out gout in acute cases merely by negative x-ray findings. The latter may be negative even in long-standing gout. Similarly, in the early stages of tuberculous arthritis, x-ray examinations of the joints may be negative.

It is an error to diagnose gout frequently in females. Between 95 and 98 per cent of all gout occurs in males. On the other hand, one should not wait until tophi appear before diagnosing gout, as these rarely appear before the fifth to the tenth year of the disease except in very severe cases.

Other diseases may cause pains and aches in various joints or muscles. Angina pectoris, parkinsonism, brucellosis, trichinosis, hysteria, hypothyroidism, scleroderma, lupus erythematosus, cancer and many other nonarthritic syndromes may cause aches and pains in joints and muscles and may simulate rheumatoid arthritis.

Patients with coronary artery occlusion may develop a painful shoulder after a few days or weeks and in some instances may have aches and pains in the hands together with swelling of the hands and thickening of the palmar fascia. The latter may in some instances resemble Dupuytren's contracture. Conversely, spondylitis, especially with involvement of the upper thoracic region, may result in precordial distress simulating angina pectoris.

In contrast to rheumatoid arthritis the physician must realize that degenerative joint disease is almost always present in individuals past 50 years of age, especially in the lumbär, cervical and sacroiliac regions. Bauer and his associates have shown that human joints remain normal for only several decades following birth and that when hyaline articular cartilage is damaged it does not degenerate but may be repaired somewhat by the formation of fibrocartilage.

Doctors rule out degenerative joint disease too frequently merely because a negative roentgenogram is found. In many instances no x-ray abnormality may be seen despite gross pathologic changes which may be present in the articular hyaline cartilage as shown at necropsy. Articular lipping is not an essential prerequisite for the diagnosis of degenerative joint disease. Extensive hypertrophic spinal changes may be found without symptoms. It is unusual to examine the spine roentgenologically in an individual past 50 years of age without finding some evidence of degenerative joint disease. In most instances such changes do not produce symptoms.

The physician should always explain to the patient that Heberden's nodes are not a sign of rheumatoid arthritis but are a manifestation of degenerative joint disease. Many persons with Heberden's nodes give a family history of these. One must assure these patients that they will not go on to helpless crippling and deformity such as may occur occasionally in some cases of rheumatoid arthritis but that the process is one of heredity coupled with age, wear and tear and that it will not lead to any especial persisting pain or to severe deformities. Heberden's nodes usually worry a patient more because of their unsightly appearance than because of their great degree of disability.

In patients with pain in the low back, the causation of such pain is often attributed to arthritis merely because there are hypertrophic changes in the lumbar vertebrae or sacroiliac region. In most instances backache is due to ligamentous and muscular strain. It has been shown that practically 50 per cent of all patients with architectural weakness of the spine have no symptoms whatever resulting from such a disturbance. It is a mistake to believe that because trauma to the low back has been minimal the resulting symptoms will be slight. The symptoms of lumbosacral strain may be out of all proportion to the trauma involved.

Low back pain is often wrongly attributed to the presence of congenital abnormalities found on roentgen examination. More than one third of all spines x-rayed for any purpose may show congenital abnormalities; however, in most instances the latter do not cause the patient's symptoms, although they may aggravate these.

Another common error is to believe that all low back pain is due to herniated intervertebral disks. Although the latter are extremely popular at the present time, these cause only a small proportion of all low back pain seen by the general practitioner.

Pain radiating down the legs is frequently diagnosed as sciatica. Sciatica is not a disease but is merely a symptom designating pain in the distribution of the sciatic nerve. It is no more a diagnosis than is headache.

It is also a mistake to omit roentgen examinations of the low back in individuals with persisting low back pain. Any persisting or recurring painful back deserves proper x-ray studies. The physician must realize that a correct diagnosis is essential in the successful treatment of low back pain. This often requires careful study of the patient together with a painstaking physical examination and in some instances additional tests, including x-rays of the low back.

Shortening of one leg and improper weight distribution may be important factors, aggravating or initiating persisting low back pain. In addition, the feet are often ignored. Chronic foot strain is an extremely common cause of pain not only in the foot and lower leg but also in the knee and low back.

Pronounced damage may result occasionally from a single injury. Injury may be a cause of joint discomfort even in the absence of evident anatomic changes. A single strain or contusion may produce years of pain and limitation of motion.

Another common mistake is to consider all spur formation on the os calcis as due to gonorrheal arthritis. Most spurs on the os calcis are not associated with gonorrhea. Gonorrheal arthritis may be present in individuals who have no symptoms referable to the genitourinary tract. It is also an error to believe that gonorrheal arthritis commonly involves the sterno-

clavicular, temporomandibular or spinal joints. Such involvement is relatively uncommon. However, conjunctivitis and tenosynovitis are extremely common in association with gonorrheal arthritis; this is not generally recognized.

One must not forget that joint damage may be due to syphilis. Syphilis may mimic any form of joint disease from the bilateral hydrops of the knees in children (the so-called Clutton's joints) all the way to the Charcot joint. Joint involvement in syphilis may become increasingly infrequent with the introduction of penicillin and massive arsenotherapy in the treatment of syphilis. One should always request a serologic test for syphilis in any patient with joint aches and pain.

Most physicians are apt to misdiagnose neuritis or arthritis in persons with a history of a painful shoulder. It is extremely uncommon to find an arthritis which develops in the shoulder joint except in association with arthritis in other regions of the body. Likewise, neuritis involving only the upper arm is extremely uncommon in comparison with the frequency of subdeltoid bursitis or periartthritis of the shoulder—the most common lesion about the shoulder joint. In most instances this lesion is due to small tears, hemorrhages or calcification in the supraspinatus tendon with secondary involvement of the subdeltoid bursa. Any lesion about the shoulder which causes pain may be associated with spasm of the scalenus anticus muscle with its characteristic group of symptoms including pain in the shoulder, together with pain and numbness radiating in many instances to the elbow or to the finger tips.

Unfortunately, there are insufficient funds in this country for investigative work and inadequate hospital facilities for the care of arthritic patients. There are not more than 200 free beds in the United States for rheumatic patients as contrasted with approximately 100,000 free beds for the care of tuberculous patients, despite the fact that arthritis and allied conditions affect more persons in this country than the sum of all patients having tuberculosis, cancer, diabetes and heart disease. We must have hundreds of small and large hospitals scattered throughout the United States under the supervision of trained personnel and devoted solely to the study and care of arthritis and allied conditions. The medical profession should attempt, as soon as possible after the present conflict, to utilize some of the present army hospitals as centers for the study and care of arthritic patients. This is probably our most pressing need in the care of such patients at the present time.

One of the mistakes commonly made by practitioners in the treatment of arthritic patients is to depart from recognized remedies. As there is no specific drug which will cure all cases of rheumatoid arthritis, practitioners frequently resort to many widely advertised, but usually ineffective, remedies in the handling of these patients. The physician must realize that when using therapy which is not accepted by the majority of physicians in his vicinity he does so at his own risk and peril, and if such departure results in injury to the patient so treated the physician is liable for the damage despite how good his intentions may have been.

We do not have a specific magic bullet for the treatment of rheumatoid arthritis. The practicing physician should not be misled by overenthusiastic statements which may appear in the advertisements of some drug houses. On the other hand, he must not be pessimistic concerning the outlook in the arthritic patient.

The treatment of rheumatoid arthritis requires months or years of careful management, and it is a

mistake to tell the average patient that he will be greatly improved within a few days or weeks. The physician must manifest an honest degree of optimism in handling these patients. He must never promise a cure in rheumatoid arthritis, but the patient can be told that with proper care he has about nine chances out of ten of being definitely benefited.

The patient must not be led to believe that his improvement will be steady and uninterrupted, as changes in weather, emotional upsets and other factors may produce exacerbations of the disease despite every effort to avoid these.

A common mistake in the handling of arthritic patients is to treat the joints and to neglect the patient's general health and comfort. One must always remember that one is treating a human being and not merely a few joints. The patient with rheumatoid arthritis may develop a sinusitis, bronchitis, acute appendicitis or other ailments, either organic or functional, which demand treatment just as much as does the arthritis.

The patient with rheumatoid arthritis should not be told to go to bed for prolonged periods without proper exercise and massage. If the patient lies in bed like a lump of putty, much harm can be done. Adequate periods of rest each day are of extreme importance in the handling of most patients with rheumatoid arthritis. If it is advisable for the patient to spend several hours or more in bed each day, the physician must prescribe very carefully and must outline in detail exercises which should be done by that individual. A member of the patient's family should be trained as well as possible to give massage daily in addition to periodic massage by a trained masseuse. The amount of time required and the type of massage vary from patient to patient. Exercises likewise must be prescribed for the individual and must be particularly suited to his case.

Some patients with rheumatoid arthritis move their joints as much as possible in an attempt to avoid deformities and to prevent the joints from becoming stiff. Excessive motion of the affected joints in these patients in the acute stage of the disease usually leads to further damage of the joints and to increased pain, swelling and stiffness. One must carefully balance the amount of rest and exercise in an individual. Each patient should have sufficient exercise to prevent stiffness of the affected joints and sufficient rest to permit healing. A good general rule in this respect is never to exercise the affected joints to the point of persisting pain or fatigue.

Many mistakes are made in the use of physical therapy. Physical therapy alone will not cure most cases of arthritis. On the other hand, physical therapy should never be omitted in the treatment of average arthritic patients, particularly those with subacute or chronic forms of arthritis.

Physical therapy in rheumatoid arthritis should not be given only two or three times a week in the physician's office or in the hospital. This should be carried out daily if possible. A routine should be prescribed which can be continued in the patient's home, supplemented by additional physical therapy at the office or hospital as indicated.

Although most patients with rheumatoid arthritis are grateful for the application of heat, one should not continue to apply heat to the patient if this makes him worse. The beneficial effects from diathermy or short wave therapy are not due to any specific biologic or

bactericidal action. Some physicians make the mistake of permitting the patient to regulate the current in diathermy treatments, and occasionally a physician applies diathermy electrodes to the broken skin.

One of the worst mistakes that is made in cases of rheumatoid arthritis is to permit pillows to be placed under the knees. If the knees are involved in the arthritic process, every attempt must be made to keep the knees extended; pillows under arthritic knees will lead to contracture deformities.

Similarly the patient should not walk with a deformed, flexed knee joint when this can be straightened; walking with the knee flexed may produce distortion in both the lower extremities and in the trunk. It is easier to prevent a deformity than to correct one.

All physicians should be willing to learn to use plaster in their cases of arthritis. The internist will find that there is less danger of ankylosis if joints are properly splinted than if they are constantly moved.

One should not permit splints to remain in place for long periods without removing them. In cases of rheumatoid arthritis the splints should be removed at least once a day and the affected joints moved through at least two or three full painless motions to prevent the formation of dense adhesions.

Joints that are acutely inflamed should not be manipulated. These should be kept at rest as much as possible. In such cases when muscular exercises are begun they should be performed slowly, because rapid motion quickly produces fatigue in muscles and rapid sudden jerky movements may produce further damage to arthritic joints.

The general practitioner should not administer gold salts without first studying carefully the reactions which may occur following their use, as well as the indications, contraindications and proper dosage for best results. Gold may be toxic and certainly is not the final answer to the treatment of rheumatoid arthritis. Some patients are not improved following adequate gold therapy, and others may develop toxic reactions; in some, relapses may occur following the termination of the course of gold therapy. It is generally believed that gold therapy in rheumatoid arthritis is still too dangerous to be employed by the practitioner without previous special instruction and careful study.

Some physicians still employ large doses of gold salts. Our results when using only 25 mg. of the gold salt have been as good as when using 100 mg. (as was formerly given) at each injection. Using the smaller dose, toxic reactions have been reduced enormously and such reactions, when they occur, are usually mild and of short duration.

Gold salts should not be given in any form of joint disease except rheumatoid arthritis. They are of no value in the treatment of degenerative joint disease, gout, fibrositis, specific infectious forms of arthritis or rheumatic fever. One should not continue using gold if the patient shows any untoward reaction, no matter how mild this may be. The unpredictable nature and time of the toxic reactions following gold therapy are the chief hazards in their use.

One cannot predict which patients will develop signs of toxicity or complications from gold. Either the patient or his family must be informed in advance of treatment of the possibility of toxic reactions.

It has never been shown that any particular form of vitamin deficiency produces rheumatoid arthritis. Some physicians prescribe massive doses of vitamin D in the treatment of rheumatoid arthritis. Most arthritic clinics

in large teaching hospitals no longer routinely employ massive doses of vitamin D in the treatment of this disorder. The Council on Pharmacy and Chemistry has stated that clinical evidence does not warrant the claim that massive doses of vitamin D are of benefit in chronic arthritis. It is a mistake to use massive doses of vitamin D without realizing that toxic symptoms may arise following its use. There is a definite risk of renal damage in addition to frequent gastrointestinal upsets.

Another common mistake in the handling of patients with rheumatoid arthritis is to advise the patient to give up his job, sell all his belongings and move to the Southwestern part of the United States in the hope that he will be miraculously and suddenly cured of his rheumatoid arthritis. Unfortunately, such does not occur. In most cases of rheumatoid arthritis, change in climate alone will usually not result in definite improvement in the arthritic picture. Holbrook has found that chronic arthritis may continue as a sad and crippling disease even on the Arizona desert. Hench has advised that most patients with rheumatoid arthritis should battle their arthritic problems at home and should not be encouraged to endanger their economic status or disrupt their social ties in a vain attempt to seek a climate that cures. This does not apply, however, to rheumatic fever, as these patients will usually be distinctly improved by a residence in the tropics or in the Southwestern part of the United States, Puerto Rico or similar regions. However, a tropical climate will not cure rheumatic heart disease and will not remake damaged valves. Likewise it will not influence cardiac decompensation.

Unfortunately it is the general belief of many patients and of some physicians that a stay of twenty-one days or more at a spa will cure rheumatoid arthritis. Many persons with rheumatoid arthritis may be greatly improved by hydrotherapy and by a vacation away from home. However, the physician must not mislead his patient with rheumatoid arthritis to make a great financial sacrifice unnecessarily. Buoyancy is present in the water in any bathtub whether the patient is at home or in a high priced spa. Furthermore, it has never been shown conclusively that mineral baths or applications of mud are particularly beneficial because of absorption of minerals or salts from these. As yet we have no good proof that appreciable amounts of any element are absorbed from mineral waters or muds.

Another common fallacy is to believe that a specific diet will cure most cases of rheumatoid arthritis. There is no proof that any particular diet will lead to the production of rheumatoid arthritis or that a specific diet in itself will cure rheumatoid arthritis. Most physicians treating these patients now employ a sensible high caloric, high vitamin, anticonstipation regimen, including at least several glasses of milk per day, fresh green vegetables, fresh citrus fruits or fruit juice and adequate protein together with other foods to make up the caloric requirements.

Most internists believe that it is unwise to permit a definite focus of infection to remain if this can be eradicated without detriment to the patient. While the removal of focal infection per se seldom produces much improvement in the patient with rheumatoid arthritis, such a procedure may lessen the burden which the patient is carrying. We do not yet know the role of focal infection in most cases of rheumatoid arthritis.

Unfortunately, most medical men have but little knowledge concerning the teeth and their disorders;

however, they do not hesitate to tell the dentist which teeth must be extracted. It is hoped in the future that the dentist will be considered as a consultant and not merely as a mechanic. Frequently the physician will order extraction of all pulpless teeth in an arthritic patient despite the fact that there is no more evidence to warrant their extraction from a patient with rheumatoid arthritis than from a patient without arthritis. On the other hand, a negative roentgenogram of a pulpless tooth does not eliminate the tooth as a possible source of infection.

It is always a mistake to tell the patient or his family that the removal of a focus of infection will cure his rheumatoid arthritis; improvement will result in only a small percentage of patients following this procedure.

Many patients with rheumatoid arthritis require analgesics, especially in the early stages of their disease. Although some physicians employ analgesics in these cases, the dose is usually insufficient to relieve the pain or discomfort. It is often necessary to employ at least 0.3 Gm. of acetylsalicylic acid and of acetophenetidin two or three times a day and again at bedtime in order to produce temporary symptomatic relief. A small dose of acetylsalicylic acid alone will usually not relieve the pain and will thus leave the patient pessimistic concerning the outlook for his joints. Although aminopyrine will usually relieve pain in patients with rheumatoid arthritis as well as in those with rheumatic fever, it is inadvisable to use this drug routinely because of the possibility of the production of agranulocytic angina.

It is almost always a mistake to give narcotics to patients with rheumatoid arthritis, except as an emergency measure in a very few instances. If it is necessary to employ narcotics over a long period of time, one should check the diagnosis as this is probably in error. A prolonged need for narcotics for a patient with joint symptoms suggests the probability of a neoplasm.

Some physicians have advised their female patients with rheumatoid arthritis to become pregnant, as pregnant patients often notice a decided amelioration of their rheumatoid arthritis. This is often a mistake; although the patient is relieved of many of her arthritic symptoms during the pregnancy, the joint pain, swelling and stiffness usually return in a more aggravated form within four or six weeks following delivery. Less than 10 per cent of patients with rheumatoid arthritis who become pregnant are relieved of their rheumatoid arthritis for long periods following delivery.

Injections such as vaccines, sulfur, chaulmoogra oil or foreign protein will not straighten chronically deformed, ankylosed joints. Although these preparations may be of some benefit as a psychotherapeutic measure, they have not been proved to be of permanent value in the treatment of most cases of rheumatoid arthritis. Recent work has shown that injections of sterile saline solution will produce symptomatic benefits as great as the benefits derived from injections of specific or nonspecific vaccines.

The practitioner must realize the importance of the general problem of arthritis. With a correct early diagnosis and thorough and proper treatment, many of these patients will be greatly benefited and most deformities may be avoided. The physician must not look on the arthritic patient merely as another candidate for a series of injections of drugs of doubtful value, but he must develop a well rounded program of therapy which will vary with each patient depending on the peculiarities of that case. In addition, the medical

TREATMENT OF A PERFORATING CORNEAL WOUND
WITH PENICILLIN AND SULFADIAZINE

NELL WHITE SANDERS, M.D., BALTIMORE

Small, dirty perforating wounds of the eye generally have rather grave consequences. This case is reported because not only was it a serious type of injury but there was much delay in beginning treatment.

M. O'R., a white man aged 78, first seen in the dispensary on July 9, 1944, stated that on July 5, while at work, he was struck in the left eye with a piece of bailing wire. He stated that the eye gave him no trouble until July 8, when it became painful and inflamed. On that day he applied for treatment at one of the general hospitals, where he was instructed to report to us immediately but did not find his way here until the following day.

The patient's past history was noncontributory. Although he was 78 years old he was still doing a "day's work." Physical examination was negative except for the findings in the left eye. On examination of the left eye the lids and adnexa were clear. The bulbar and palpebral conjunctiva was much injected. About 3 mm. from the limbus, opposite 6 o'clock, there was a puncture wound of the cornea with an ulcer about 2 mm. in diameter surrounded by an area of keratitis. A hypopyon about 5 mm. in depth and extending across the lower part of the anterior chamber was present. The presence of the hypopyon made it impossible to ascertain whether or not the iris was damaged. The pupil was not dilated; there were deposits of exudate on the lens capsule. The fundus could not be visualized. Finger tension was normal. The patient was able to recognize only hand movements.

He was hospitalized and placed on the orthodox sulfadiazine therapy: 2 Gm. immediately and 1 Gm. every four hours, with an equal amount of sodium bicarbonate. Fifteen hundred units of tetanus antitoxin was given on admission. Local applications in the form of hot compresses every two hours and atropine 1 per cent three times a day were used. His temperature was normal on admission and at no time during his hospital stay was he febrile. Hematologic studies approached normal, hemoglobin being 98 per cent (Sahli) with 4.35 million red cells per cubic millimeter. At no time during his hospital course did he show an increase in white cell count, and the differential was always within normal limits. A culture made from corneal scrapings at the point of penetration showed hemolytic *Staphylococcus albus* and nonhemolytic streptococcus.

Four days after admission to the hospital the eye was showing no improvement whatever with sulfadiazine therapy; the hypopyon was becoming larger and the whole inflammatory process was extending. We felt that unless something was done to arrest the process it would be necessary to enucleate the eye. Two thousand five hundred Florey units of penicillin was injected subconjunctivally. It was decided to use the penicillin subconjunctivally in an effort to build up quickly a good concentration at the point where it was most needed. The penicillin was made up in sterile distilled water so that each cubic centimeter contained 10,000 units, and then 0.25 cc. was injected subconjunctivally at a point opposite the hypopyon and near the limbus after five instillations of 0.5 per cent pontocaine at ten minute intervals had been used. Despite what should have been ample anesthesia, the injection was quite painful. Following the injection of penicillin the hypopyon did not become larger but remained stationary. Penicillin was then used as drops directly into the conjunctival sac, being instilled every two hours. During the time the penicillin was being used locally the sulfadiazine also was continued. After the penicillin had been used for three days it became apparent that local application was not adequate and penicillin intravenously, 10,000 Florey units, was given every three hours. It

was planned to continue the sulfadiazine along with the penicillin, but after four days it was necessary to discontinue the sulfadiazine because of hematuria. The penicillin was continued, 10,000 Florey units every three hours, for one week. At the end of this time it appeared that the exudate in the anterior chamber was becoming organized and it was decided to do a paracentesis in the hope that the formation of new aqueous would also furnish new antibodies. The paracentesis was done by introducing a keratome into the anterior chamber at the limbus opposite 4 o'clock. Much of the exudate drained out of the anterior chamber at the time of the operation, and for several days after it the wound was reopened with an iris reposer. Following this procedure the remaining exudate began to absorb, and while the penicillin was continued for an additional three days after the operation the patient was so much improved that the penicillin was discontinued and sulfadiazine therapy was reinstituted.

A total of 700,000 units of penicillin was used in conjunction with 77 Gm. of sulfadiazine. The sulfadiazine level was at no time above 10.4 mg. per hundred cubic centimeters and it was maintained around 4 or 5 mg. per hundred cubic centimeters for the greater part of the time.

After one month and four days in the hospital the patient was discharged, at which time his eye was clear, there being only slight injection of the bulbar conjunctiva and a small opacity of the cornea at the site of puncture. The pupil was not widely dilated, and a small amount of exudate remained on the lens.

Ten weeks after being discharged from the hospital the patient reappeared in the clinic. At that time the eye was clear; that is, the conjunctiva was white. There was a small opacity of the cornea below the pupillary area opposite 6 o'clock and about 3 mm. from the limbus. The pupil was about 2.5 mm. wide and did not react to light, being fixed by a membrane extending across the pupil. Vision in the eye was 5/200. The patient stated that he was working every day and that the eye was giving him no trouble.

SUMMARY

A patient was seen with a well developed hypopyon and other manifestations of an enophthalmitis. He was treated with a total of 77 Gm. of sulfadiazine and 700,000 Florey units of penicillin. While his recovery was not sudden and spectacular, the eye was saved.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

METYCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1944, p. 82).

The following additional dosage form has been accepted:
ELI LILLY & CO., INDIANAPOLIS

Metycaine Hydrochloride Ointment 5%: Metycaine hydrochloride 5 per cent in a base consisting of white petrolatum with white wax and wool fat.

TYROTHRIN (See THE JOURNAL, April 1, 1944, p. 985).

The following dosage form has been accepted:

PARKE, DAVIS & CO., DETROIT

Solution Tyrothricin 2% W/V: 10 cc. vials. Each cubic centimeter contains 20 mg. of tyrothricin in alcohol 92 per cent.

From the Baltimore Eye, Ear and Throat Hospital, Baltimore 17.
All penicillin used in this case was obtained from Maryland General Hospital, Howard and Madison streets, Baltimore, a depot for the distribution of penicillin for civilian use.

HEALTH INSURANCE LEGISLATION IN CALIFORNIA

In the Organization Section in this issue of THE JOURNAL appears an analysis of various proposals made to the 1945 legislature of the state of California relative to the care of the sick. The analysis covers only bills introduced before Jan. 27, 1945, although there are altogether some thirteen bills now before the legislature dealing with various aspects of medical care. The measure proposed by the Congress of Industrial Organizations would create a California health insurance commission on which there would be one physician out of a total of nine members. The state would be divided into areas, in each of which there would be directors, councils, appeal bodies and similar agencies typical of the expansive bureaucracies inevitable under such a plan. Attempts have been made in this proposal to meet the ideas of free choice of physician and fee for service when that is given by specialists.

An alternative proposal from Governor Warren of California provides an authoritative body containing eleven members and a manager (all to be appointed by the governor), and this time with two practicing physicians and one experienced in hospital management. In both Governor Warren's proposal and that of the C. I. O. the tax is 1.5 per cent on the employer and a similar amount on the employee. Payment is to be in accordance with a fee schedule adopted by the governing body, with free choice of physician from among such as will register under the act. Governor Warren's measure exempts, both from the benefits and from the taxes, people who depend on healing by prayer. The bill also exempts, both from the benefits and from the taxes, any industrial medical plan which contracts with the authority to continue its work. This would enable the Kaiser plan, for example, to escape the provisions of the act and to maintain its system of practice by a closed group of physicians under contract to the system. The authority given under the governor's proposal to the medical authority which is established is greater

than that ever given to any similar group, since it is authorized to expel from practice under the act any physician who intentionally violates any rule or regulation of the authority.

An assemblyman introduced into the California legislature a bill identical with the compulsory sickness insurance bill sponsored by Governor Olson in 1939. This sets up a division of medical service in the Department of Employment, is financed by a 1 per cent tax on employer and employee, and proposes to give complete medical service.

The California Medical Association offers a measure which proposes to aid and assist existing voluntary nonprofit plans. It does not contemplate any new taxes. The effect of this measure would be to stimulate tremendously enrolment by workers of the low income and middle income groups in voluntary plans.

A careful reading of these measures will indicate that the answer is not yet. The problem of establishing medical care for all under prepayment plans, either voluntary or compulsory, is complex and susceptible to various detrimental influences. Much carefully controlled experimentation with voluntary plans such as now prevails in many parts of the country is needed before anything resembling a real answer to the problem of medical care for all the people will be forthcoming.

ARTIFICIAL INDUCTION OF LACTATION IN BOVINES

Folley and Malpress,¹ working at the National Institute for Research in Dairying, University of Reading, in England under a research grant from the Agricultural Research Council, were able to induce lactation in nulliparous heifers and dry cows by the subcutaneous implantation of large numbers of small tablets of diethylstilbestrol or hexestrol. Individual variations and responses were large, but in some cases the lactation curve was comparable with that of normal lactation. The best response was obtained with a dry cow which gave a maximum yield of 30¼ pounds daily and a total yield of 7,400 pounds. Implants totaling 5 and 2.5 Gm. were equally effective and there appeared to be no difference in efficacy between diethylstilbestrol and hexestrol. Copious lactation was also induced in nulliparous heifers and dry cows by the subcutaneous implants of one or two tablets of hexestrol weighing approximately 1,000 mg.

The estrogen treatment was in most cases accompanied by a nymphomaniac syndrome which to a varying degree was exhibited by most animals under experiment. In 20 per cent of the experiments in which small tablets were implanted this nymphomaniac syndrome resulted in fracture of the pelvis, necessitating the slaughter

1. Folley, S. J., and Malpress, F. H.: The Artificial Induction of Lactation in the Bovine by the Subcutaneous Implantation of Small Estrogen Tablets. *J. Endocrinol.* 4: 1 (July) 1944.

of the affected animals. The fractures appeared to have occurred during coital mimicry, a usual feature of the nymphomaniac syndrome. Since there was no evidence of decalcification of the pelvis² the fractures would not have occurred in all probability had the animals in question been kept under isolation during the period of treatment.

The mammary secretions produced by heifers artificially brought into lactation by treatment with synthetic estrogens were at the outset colostrum in nature,³ but the composition gradually changed to that characteristic of milk of good chemical quality at the rate proportional to the rate of increase in yield. In general, a daily yield of 5 pounds could be regarded as a guaranty of normal composition.

Hammond and Day⁴ performed similar experiments at the School of Agriculture at Cambridge on 140 cows and heifers, utilizing the implant method of tablets of diethylstilbestrol or hexestrol. They found that during treatment follicle growth ceased and occasionally the corpus luteum persisted; after removal of the implant follicle growth began and ovulating was resumed, sometimes after a transient period of follicular cysts. The heifers used were animals which had failed to get in calf. After treatment a number of those with normal organs were subjected to copulation and a large proportion got in calf. Mammary growth in heifers has occurred. Lactation has not resulted in every case, and sometimes the volume of secretion was low, but many animals have given commercial yields.

These experiments indicate that copious lactation may be initiated in maiden heifers and dry cows in a useful proportion of cases by the subcutaneous implantation of solid tablets of synthetic estrogens. Two main processes are involved in the lactation response, growth of the mammary gland followed by initiation and maintenance of lactation. Probably on the basis of analogy with experiments on small animals, progesterone is needed for full alveolar development in the bovine as well as estrogen. However, the interpretation of evidence regarding the necessity or otherwise for the precipitation of progesterone in mammary growth has been complicated by the isolation of progesterone from the adrenal cortex. Since no corpora lutea were found during treatment in the ovaries of the bovines used in these experiments, Folley and Malpress argue that the only source of progesterone would therefore appear to be the adrenal cortex. On the assumption that progesterone is necessary for full mammary development in the bovine, it is conceivable that insufficient mammary

alveolar development due to deficiency of progesterone may have been a limiting factor in some cases in which the lactation response was possible. Even in the presence of ample progesterone, if the estrogen dosage was excessive or too prolonged, mammary development may have been curtailed or of an abnormal type, so that the secretory power of the gland would have been sub-optimal. In fact, Gardner has described inhibition of mammary growth in various species by high doses of estrogens. The experiments of the authors provide evidence that estrogen will stimulate the production of lactogenic and galactopoietic hormones by the anterior pituitary under suitable circumstances provided the dosage is not too high.

FLUORINE AND FRACTURES

Twenty years ago attention was directed to the discovery of fluoride in domestic water supplies as the causative factor in dental fluorosis, or mottled enamel.¹ In the intervening period intensive investigation has been made of the physiologic chemistry of this element with respect to its influence on the skeleton, its metabolic effects and its relation to dental caries. In view of the observation² that fluorine in the drinking water is correlated with a significant decrease in dental caries, suggestions have been made that fluoride be added to city water supplies in areas where this element is absent. However, the need for caution has been repeatedly expressed, as several less desirable effects of ingested fluoride have been noted. One of these is the decrease in breaking strength of bones when fluoride is present in the diet.

A recent study of the influence of fluoride in domestic water on height, weight and fracture experience affords important data on this question.³ Taking advantage of the vast quantity of statistics accumulated in connection with the induction of young men into the armed forces, McClure compared the data for height and weight of 2,529 selectees, some from areas where the drinking water contains fluorine and some from areas whose water was free from fluorine or below the known level of dental fluorosis. In like manner 1,458 high school boys were studied. In addition, statements were obtained from each subject regarding bone fractures such as are encountered in various sports. After correlating the data on height, body weight and fractures with the broad spread of concentrations of fluorine in the water drunk by the subjects, the conclusion was reached that fluorine in the water has no effect on height or weight and appears to exert no serious impairment in skeletal performance such as might be manifest in broken bones.

2. Dean, H. T.; Arnold, F. A., Jr., and Elvove, E.: *Pub. Health Rep.* 57: 1155 (Aug. 7) 1942.

3. McClure, F. J.: *Pub. Health Rep.* 59: 1543 (Dec. 1) 1944.

The urine of a large proportion of the same subjects was examined for fluoride concentration.⁴ In localities where the water was free of fluorine the average concentration in the urine is 0.3 to 0.5 part per million. With increasing amounts of fluorine in the water there occurred proportional increases in the urine. It appears from the foregoing observations that normal renal function is a safeguard against suspected toxic bone fluorosis in adult human subjects even in regions where the potable waters contain appreciable amounts of fluorine.

Current Comment

TREATMENT OF PLANT DISEASE WITH PENICILLIN

The first successful application of penicillin to phytotherapy is reported by Brown and Boyle¹ of the Agriculture Experiment Station, Tucson, Ariz. The plant disease treated by them was crown gall of *Bryophyllum*, caused by local inoculation with a pure culture of *Agrobacterium tumefaciens*. The penicillin preparation used for treatment was a crude product which assayed but 2 to 6 Oxford units per cubic centimeter. Penicillin soaked cotton was wrapped round the galls and the gall then punctured in numerous places with a sterile needle. The gall tissues began to turn brown soon after treatment. Complete destruction of the gall followed, with negligible injury to the surrounding normal plant tissues. On account of the economic loss from crown gall in the Southwest, the Arizona investigators recommend the application of penicillin therapy to set trees and nursery stock. Crude penicillin can be prepared by the Clifton² technic at a cost of about 2 cents a quart. Only a tablespoonful is required for a cure. Their findings are of suggestive clinical interest, since the crown gall bacterium is gram negative. Thus far many clinicians have assumed that all gram negative bacteria are refractory to penicillin.

EPIDEMIOLOGY OF VENEREAL DISEASES

The venereal diseases are communicable and are therefore subject to epidemiologic control. For this three general methods have been outlined recently by Gordon.¹ Where feasible the destruction or elimination of the reservoir of infection is most satisfactory; second is breaking the chain of infection at the point of transfer; finally, measures may be employed which will increase the resistance of the individual and thereby the resistance of the "herd." An adequate program for medical care of the persons suffering from either of the two most common venereal diseases, Gordon says, would effectively eliminate them, provided such facilities were known to all persons, that those who needed them were conscious of the need

and that the facilities would be used voluntarily. Unfortunately the mere providing of medical care is not enough. The community as a whole, Gordon says, must be responsible for education of the individual concerning the venereal diseases, for epidemiologic studies necessary to define the extent of the problem and to expose the points most open to attack, and for providing those control measures which can function only as a community responsibility. Case finding by investigation of contacts has proved highly successful whenever trained personnel are available, even in the face of great practical difficulties. Quarantine of known contacts is a recognized method which is practical in dealing with the infectious prostitute but not with the casual source of infection. Other methods of epidemiologic control consist of house to house canvass, the periodic physical examination and notification by physicians to health agencies as is done with other communicable diseases. The epidemiologic approach to the control of the venereal diseases is not new, but the experience gained with the armed forces and the communities in which large army camps have been located, both in this country and abroad, should prove of great value after the war as well as now.

CONTROL OF ALLOXAN DIABETES IN RATS BY HIGH FAT DIET

In rats and other animals diabetes can be produced by the injection of alloxan and its action on the pancreatic islets.¹ Closely related to the purines, alloxan may be formed in the course of metabolism in the body and possibly may be a cause of human diabetes. That alloxan is of great value for the experimental study of diabetes is illustrated by the work of Burn, Lewis and Kelsey² of the department of pharmacology at Oxford University on the control of alloxan diabetes in rats by a high fat diet. These investigators made rats diabetic by injecting alloxan and then found that on a high fat diet "the glycosuria disappeared and remained absent until the normal diet was resumed." Abrupt change to a fat diet was accompanied by some ketonuria, but on a gradual increase of fat in the diet the glycosuria disappeared without the development of any ketonuria. "After successive periods of high fat diet the glycosuria seen on return to the normal diet steadily diminished." In other words, alloxan diabetes in rats can be controlled by diet. In the treatment of human diabetes the possibility of ketonuria and coma prevents the use of high fat diets, which in fact have been recommended by Allen and others.³ Undoubtedly the results of the Oxford investigators in the dietary control of diabetes in rats will stimulate renewed interest in the dietary control of human diabetes and in the problems of ketonuria.

MEDICINE AND THE WAR

ARMY

TEN RECEIVE AMERICAN TYPHUS COMMISSION MEDAL

Two American ambassadors, five army officers and three navy officers were recently awarded the United States of America Typhus Commission Medal in recognition of their "exceptionally meritorious service" in the control of typhus. The recipients of the awards and the citations accompanying them include:

Hon. Alexander Comstock Kirk, United States ambassador to Italy, "for exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. As minister to Egypt during the period from Jan. 7, 1943 to May 1, 1944 Mr. Kirk took great personal interest in the activities of the commission and constantly supported its program. His support contributed materially to the success of the commission's investigations and control of typhus fever in the Middle East."

Hon. Laurence A. Steinhardt, United States Ambassador to Turkey, "for exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. During the period June 1, 1943 to May 1, 1944 Ambassador Steinhardt actively cooperated with the United States of America Typhus Commission and supported its efforts to control typhus fever in Turkey. In addition to his assistance in measures for typhus control, Mr. Steinhardt personally made possible a cooperative project with the Turkish Army Medical Department which advanced the appreciation of American medicine in Turkey and fostered scientific understanding and good will."

Capt. Thomas J. Carter, chief, Preventive Medicine Division, Bureau of Medicine and Surgery, Navy Department, Washington, D. C., "for exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. In December 1942, before he was a member of the commission, Captain Carter was commended for the assistance he rendered during the organization of the first overseas movement of the commission. Since January 1943, as a member of the executive committee of the commission, he has constantly contributed sound judgment, expert professional knowledge and personal attention to the participation of the United States Navy in the activities of the commission abroad and in this country. His services have been invaluable to the operation of the commission as a whole and have contributed to the investigation and control of typhus fever." Dr. Carter graduated from Jefferson Medical College of Philadelphia in 1927 and entered the service June 27, 1927.

Col. Harry Plotz, formerly of Brooklyn, "for meritorious service in connection with the work of the United States of America Typhus Commission. Arriving at Cairo, Egypt, in January 1943, Colonel Plotz organized and directed the first laboratory provided abroad for the commission's investigation of typhus fever and for the laboratory training of Egyptian physicians. Since his return to this country he has continued to serve the commission through his capacity as chief of the Virus and Rickettsial Diseases Division of the Army Medical School. To a long and distinguished career in typhus research he has added renown by new accomplishments." Dr. Plotz graduated from Columbia University College of Physicians and Surgeons, New York, in 1913 and entered the service Jan. 10, 1941.

Lieut. Col. John C. Snyder, formerly of New York, "for exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. The development of the commission's research and diagnostic laboratory at Cairo, Egypt, is largely to be attributed to the vision, devotion and energy of Lieutenant Colonel Snyder. Since early in 1943 he has devoted himself unremittingly to the laboratory and clinical investigation of typhus fever. With interests extending beyond the laboratory, he has participated in the

development and trial of promising new methods for the serum therapy and chemotherapy of typhus. He applied his expert clinical and laboratory knowledge to the actual control of typhus fever during the outbreak of the disease at Naples, where he had charge of the organization and operation of the case finding service. One of the few thoroughly qualified research workers in the field of typhus in America, Lieutenant Colonel Snyder has devoted himself untiringly to laboratory and clinical investigations which have resulted in new knowledge and increased power to control typhus fever." Dr. Snyder graduated from Harvard Medical School, Boston, in 1935 and entered the service Nov. 22, 1941.

Lieut. Comdr. William B. McAllister Jr., formerly of Cleveland Heights, Ohio, "for exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. Beginning as pathologist in the first expeditionary group of the commission in 1943, Lieutenant Commander McAllister has conducted scientific investigations of typhus fever in Egypt. In addition, his surveys of the typhus situation in several Middle East and North African countries provided basic information for the operation of the commission. For more than a year he has served with remarkable success as executive officer of the section of the commission in the Middle East. In the absence of the Field director he has been the chief officer of the commission at Cairo and in that capacity has dealt with administrative problems of great complexity and importance. Through both his scientific investigations and his administrative skill, Lieutenant Commander McAllister, serving with notable loyalty and devotion to high purposes, has made an essential contribution to the commission and to the advancement of the knowledge and control of typhus fever." Dr. McAllister graduated from John Hopkins University School of Medicine, Baltimore, in 1939 and entered the service Sept. 2, 1941.

Major Charles M. Wheeler, Sanitary Corps, A. U. S., formerly of Brea, Calif., "for exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. Ever since he became a member of the commission in 1943, Major Wheeler has pursued a straightforward and highly effective course in the investigation, improvement and application of delousing methods using insecticides for the control of typhus. The results of his field investigations, in conjunction with other studies, have favorably influenced the entire army program. Proceeding from field studies in Egypt, Major Wheeler had charge of a main portion of the delousing program during the fight against the epidemic of typhus at Naples. He organized this work with foresight and carried it out with characteristic efficiency. Major Wheeler has rendered distinguished practical service in the actual control of outbreaks of typhus fever. Through his tact and ability in dealing with both individuals and masses of people, and through his sound judgment, courage, tireless efforts and inspiring leadership, Major Wheeler has rendered service of the highest value to his country."

Major Theodore E. Woodward, formerly of Westminster, Md., "for exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. At Casablanca, Morocco, Major Woodward, arriving with the invasion forces in 1942, instituted at once cooperative studies with French scientists at the Pasteur Institute with a view to control of the epidemic of typhus at this port and in this region. As a result, protection for American troops was enhanced. Later, as a member of the United States of America Typhus Commission, Major Woodward participated actively in the combat against typhus at Naples and in the Aden Protectorate. Finally, in a position of high responsibility he has been a representative of the commission in the European theater of opera-

tions, rendering service to military and civilian agencies before and during the invasion of Europe. Major Woodward's activities, covering a wide range of original scientific work and administration responsibilities, have been carried out with intelligence, energy, tact and devotion to the cause of protection of the military forces against typhus." Dr. Woodward graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1938 and entered the service Feb. 25, 1941.

Lieut. Comdr. Andrew Yeomans, formerly of Brookline, Mass., "for exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. Lieutenant Commander Yeomans, proceeding to Cairo, Egypt, in 1943 with the first overseas expedition of the commission, organized and operated the experimental hospital ward devoted to the study and treatment of patients with typhus fever. Under constant risk of infection, Lieutenant Commander Yeomans has furnished exemplary medical care for the patients in his ward. His clinical studies of metabolism in typhus fever are the basis for new concepts of the disease. His work on methods of treatment is opening up new possibilities both for chemotherapy and for serum therapy. Under the stress of the outbreak of typhus at Naples he participated in the commission's first survey of conditions there, furnishing information which hastened the control of the epidemic. Through assisting in control measures Lieutenant Commander Yeomans has helped to decrease the risk of typhus fever in relation to military operations. Through his unrelenting, intelligent and penetrating clinical studies he has contributed to the alleviation of suffering from typhus." Dr. Yeomans graduated from Harvard Medical School, Boston, in 1935 and entered the service in November 1942.

Capt. Byron L. Bennett, Sanitary Corps, A. U. S., formerly of Boston, "for meritorious service in connection with the work of the United States of America Typhus Commission. Proceeding to the Middle East with the first expedition of the commission, Captain Bennett assumed charge of the technical direction of the commission's laboratory at Cairo. In spite of the handicap of limited facilities, he maintained standards of technical accuracy. Later stationed at the Army Medical School, Captain Bennett has continued to serve the commission. The results of laboratory tests and research conducted by Captain Bennett have materially aided the field studies of the several main varieties of typhus fever."

8,000 WACS FOR HOSPITALS

To meet the grave challenge of mounting casualty lists and the consequently growing shortage of army nurses, General of the Army George C. Marshall has assigned to the Women's Army Corps the recruitment and training of a sufficient number of women to form 103 WAC medical units for assignment to sixty army general hospitals in this country.

To form these WAC medical units and have all 103 of them trained and functioning by midsummer, it will be necessary to enlist approximately 6,500 to 8,000 additional Wacs for work in army hospitals. The plan calls for the recruitment by training platoons of 6,170 women by May 1 for assignment to particular army general hospitals.

An accelerated training program has been set up for those women who come into the WAC for assignment to one of the training platoons. Their period of basic military training will be shortened to four and a half weeks, their course in medical technician school to six weeks, and the final period of their training will be on the job in an army general hospital. Their applicatory training in the hospital will be divided between classroom and duty in the wards for one month after their assignments to the general hospital.

LIEUTENANT JULIUS PARKER A PRISONER OF WAR

Lieut. Julius Parker, formerly of Chattanooga, Tenn., who was reported missing in action in France in December, is now reported to be a prisoner of war in Germany. Dr. Parker graduated from the University of Tennessee College of Medicine, Memphis, in 1942 and entered the service June 2, 1943.

ARMY AWARDS AND COMMENDATIONS

Colonel Marion H. Barker

Col. Marion H. Barker, formerly of Chicago, was recently awarded the Legion of Merit "for exceptionally meritorious conduct in the performance of outstanding services in the North African Theater of Operations from Jan. 21, 1944 until July 8, 1944. Assigned to the study of infectious hepatitis, Colonel Barker devised a comprehensive and effective plan of investigation and discovered valuable new data concerning its diagnosis, progress, treatment and after-effects. By his keen scientific insight and coordinated labors he developed methods of treatment and criteria for the disposition of patients suffering from this disease which prevent undue damage and restores most of those afflicted to their normal activities as healthy individuals rather than as chronic sufferers. The fighting strength of the Army has been measurably increased by this work. The investigations conducted by Colonel Barker are among the outstanding contributions to medical science during this war and are consistent with the highest traditions of research in the Medical Corps of the Army." Dr. Barker graduated from Rush Medical College, Chicago, in 1926 and entered the service Feb. 15, 1942.

Lieutenant Colonel George S. Bozalis

Lieut. Col. George S. Bozalis, formerly of Washington, D. C., has been awarded the Bronze Star Medal and recommended for the Legion of Merit for his work while with an evacuation hospital in France. The citation sets out that the enviable accomplishments of the unit may be attributed in great measure to Lieutenant Colonel Bozalis's superior professional ability and his loyal and untiring devotion to duty during operations in France. Dr. Bozalis graduated from the University of Oklahoma School of Medicine, Oklahoma City, in 1935 and entered the service in August 1941.

Captain Francis H. Fox III

The Bronze Star Medal, for distinctive service with the U. S. Army medical corps in France, was recently awarded to Capt. Francis H. Fox, formerly of Arthur, Ill. Dr. Fox's citation stated that the award was presented for "service in connection with military operation against the enemy from Aug. 8 to Aug. 25, 1944." Dr. Fox graduated from Northwestern University Medical School, Chicago, in 1936 and entered the service March 30, 1940.

Lieutenant Colonel Russell S. Wolfe

The Air Medal was recently awarded to Lieut. Col. Russell S. Wolfe, formerly of Houston, Texas, and now 7th AAF Bomber Command flight surgeon. The presentation was made by Brig. Gen. Truman H. Landon, commanding general of the 7th AAF Bomber Command. Dr. Wolfe graduated from the University of Michigan Medical School, Ann Arbor, in 1928 and entered the service Dec. 20, 1940.

Lieutenant Colonel Robert E. Daniels

For meritorious service on the field of battle in France, Lieut. Col. Robert E. Daniels, formerly of Decatur, Ind., has been awarded the Bronze Star. Dr. Daniels has been serving overseas since November 1943 as a divisional surgeon. He graduated from Indiana University School of Medicine, Indianapolis, in 1928 and entered the service Dec. 15, 1940.

Captain Clifton Felts

Capt. Clifton Felts, formerly of Seminole, Okla., recently received a citation for "heroic and meritorious duty beyond the ordinary in action" while serving as battalion surgeon in an infantry division in Italy. Dr. Felts graduated from the University of Illinois College of Medicine, Chicago, in 1932 and entered the service June 20, 1942.

Lieutenant Colonel Charles Harold Avent

Lieut. Col. Charles Harold Avent, chief surgeon of an evacuation hospital, was recently awarded the Bronze Star for meritorious service in Belgium. Dr. Avent graduated from the University of Tennessee College of Medicine, Memphis, in 1932 and entered the service June 25, 1942.

NAVY

CHANGE IN NAVY NURSE CORPS
REGULATIONS

Vice Admiral Ross T. McIntire, Surgeon General of the Navy, recently announced a modification in Nurse Corps regulations which will permit navy nurses now in service to marry without being required to resign. Liberalization of the marriage regulation is expected to help substantially in achieving the Nurse Corps's authorized strength, since more than 80 per cent of all separations from this branch of the service have been due to the marriage bar. The Navy will continue efforts, none the less, to commission 4,000 additional nurses by June 30 in order to meet needs imposed by expanding naval operations. There is no change in present policy which disqualifies married nurses for entrance into the Nurse Corps.

NEW NAVAL HOSPITAL AT DUBLIN, GA.

An 850 bed naval hospital at Dublin, Ga., was recently commissioned and has been added to the Navy's expanding list of facilities for caring for the sick and wounded. The construction program was supervised by the Bureau of Yards and Docks under Vice Admiral Ben Moreell (CEC), U.S.N. It has been designed to permit expeditious addition of new wards, if needed. Medical, dental and Nurse Corps officers killed in action since Pearl Harbor have been accorded recognition in the naming of nine main thoroughfares laid out through the hospital reservation. Capt. A. L. Bryan (MC), U.S.N., is in command of the hospital; Capt. A. J. Delaney (MC), U.S.N., is executive officer, and Lieut. Florence Carmody (NC), U.S.N., is chief nurse.

PERMANENT NAVAL DENTAL EXHIBIT

A permanent exhibit of oral diseases and maxillofacial injuries in naval hospitals may be shown throughout the country at staff Naval Dental Corps meeting in medical department facilities and at meetings of dental societies. The exhibit was collected, designed and constructed by Comdr. S. S. Wald (DC), U.S.N.R., at the U. S. Naval Hospital, Brooklyn, with the cooperation of Capt. G. E. Robertson (MC), U.S.N., medical officer in command. The exhibit consists of transparency boxes measuring 5 feet high and 3 feet wide. On the inclined sides are mounted series of 5 by 7 inch pictures in color taken by Commander Wald which illustrate procedures used in treating oral diseases and maxillofacial injuries.

BRONZE TABLET IN MEMORY OF COM-
MANDER ERIC LILJENCRA NTZ

A bronze tablet commemorating the service and untimely death of Commander Eric Liljencrantz, Medical Corps, U. S. Naval Reserve, has been set up in an appropriate place at the Naval School of Aviation Medicine, U. S. Naval Air Station, Pensacola, Fla. Dr. Liljencrantz graduated from Stanford University Medical School, San Francisco, in 1929. He lost his life in an airplane crash at the U. S. Naval Air Station, Pensacola, Fla., Nov. 5, 1942, while studying the physiologic effects of acceleration.

CAPTAIN HAKANSSON NAMED TO
MEDICAL GROUP

Capt. Erik G. Hakansson (MC), U.S.N., medical officer in command of the Naval Medical Research Institute, National Naval Medical Center, Bethesda, Md., has been named to the body of medical authorities serving on the special medical advisory group to the Veterans Administration.

NAMED PERSONNEL OFFICER OF BUMED

Capt. William Walter Hargrave (MC), U.S.N., has been named personnel officer of the Bureau of Medicine and Surgery to fill the vacancy created by the appointment of Rear Admiral W. J. C. Agnew (MC), U.S.N., to the post of assistant to the chief of the bureau.

CIVIL READJUSTMENT OFFICERS
GRADUATE

A third graduating class trained at the National Naval Medical Center in Bethesda, Md., has increased to 66 the total number of civil readjustment officers made available to the rehabilitation program in naval hospitals. The civil readjustment officers serve in all hospitals, except two where special conditions prevail, as advisers to naval and marine personnel in matters concerning their rights and benefits under existing servicemen's legislation.

NEW PLASTIC ARM SPLINT
IN USE BY NAVY

A new plastic arm splint, devised by two naval medical officers to immobilize arm fractures rapidly, is now being shipped from the naval supply depot at Brooklyn to advanced overseas areas for utilization in the evacuation of battle casualties. The splint, made of a light, strong phenolic fabric board which is resistant to moisture, was designed by Capt. French R. Moore (MC), U.S.N., head of the Combat Medical Planning Branch of the Bureau of Medicine, and Comdr. P. J. O'Donnell (MC), U.S.N.R. With the new type splint all arm and forearm fractures may be quickly immobilized, thus speeding up preparations for evacuating cases of this kind to rear area hospitals.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Commander J. Frederic Dreyer

Lieut. Comdr. J. Frederic Dreyer, formerly of Allentown, Pa., was recently awarded the Bronze Star Medal for meritorious performance of duty in the assault landings at the Bay of the Seine, France, last June 6. The citation read, in part, "The courage, decisive action and devotion to duty displayed by Lieutenant Commander Dreyer on this occasion reflect great credit on himself and the United States naval service." Lieutenant Commander Dreyer is a veteran of Allied invasions of North Africa, Sicily, Italy, Normandy and southern France and also served as censor and senior medical officer of an American amphibious command flagship which saw action in the Mediterranean theater. He graduated from the University of Toronto Faculty of Medicine in 1926 and enlisted in the Medical Corps of the U. S. Navy in September 1942.

Lieutenant Paul H. Koren

The Silver Star was recently presented to Lieut. Paul H. Koren, formerly of Scarsdale, N. Y., "for conspicuous gallantry and intrepidity as the medical officer of a beach battalion during the invasion of France on June 6, 1944. Immediately on landing on the beach at H plus thirty-two minutes, Lieutenant (then Lieutenant, Junior Grade) Koren unhesitatingly took his station at the water's edge and at constant risk of his life exposed himself to terrific German machine gun, rifle and artillery fire to minister to the wounded, carrying on his task intirringly throughout the day. His gallant spirit of self sacrifice and inspiring devotion to duty in the face of grave peril were in keeping with the highest traditions of the United States Naval Service." Dr. Koren graduated from New York Medical College, Flower and Fifth Avenue Hospital, in 1942 and entered the service in June 1943.

Lieutenant John Edward Annitto

The Legion of Merit was recently awarded to Lieut. John E. Annitto, formerly of Jersey City. The citation read "for exceptionally meritorious conduct in the performance of outstanding services to the government of the United States as medical officer assigned to an attack group during the amphibious assault on the west coast of Italy. While proceeding by small boat to a ship in the Gulf of Salerno, Lieutenant (then Lieutenant, Junior Grade) Annitto observed a nearby craft severely damaged by a direct hit from an enemy shore battery and immediately ordered his boat alongside the stricken vessel.

Although the ship was still under heavy shellfire, he went aboard and rendered first aid, continuing his work with calm courage and skilful efficiency despite the extreme danger of his exposed position. By his initiative, professional ability and unswerving devotion to duty he undoubtedly saved many lives which otherwise might have been lost." Dr. Annitto graduated from New York Medical College, Flower and Fifth Avenue Hospitals, New York, in 1937 and entered the service in September 1942.

Lieutenant Commander Carver G. Walcott

The Legion of Merit was recently presented to Lieut. Comdr. Carver G. Walcott, formerly of Fenton, Mich. The citation read "for exceptionally meritorious conduct in the performance of outstanding services to the government of the United States as medical officer attached to the U. S. S. *Biscayne* during the amphibious assault on Italy in the Gulf of Salerno, Sept. 9 to 15, 1943. By his sound judgment and expert professional knowledge Lieutenant Commander (then Lieutenant) Walcott skilfully treated survivors of nearby stricken vessels despite the danger imposed by devastating enemy bombing attacks. Working tirelessly for long periods of time aboard a small ship with

limited facilities, he effectively administered aid to a large number of casualties and, by his competent handling of a difficult task, contributed to the saving of many lives." Dr. Walcott graduated from the University of Michigan Medical School, Ann Arbor, in 1934 and entered the service June 1, 1942.

Lieutenant Frederick C. Gevalt Jr.

Lieut. Frederick C. Gevalt Jr., formerly of Boston, was the recipient of the Bronze Star recently. The citation read "for meritorious performance of duty as a company medical officer of the Second Beach Battalion during the assault on France, June 6, 1944. Lieutenant Gevalt, under heavy gunfire, repeatedly exposed himself to administer to the wounded and, without regard for his personal safety, and although wounded himself, supervised the evacuation of wounded from his section of the beach. His courage and devotion to duty were an inspiration to all officers and men having contact with him. The skill and professional ability displayed by Lieutenant Gevalt under most trying conditions were in keeping with the best traditions of the United States Naval Service." Dr. Gevalt graduated from Columbia University College of Physicians and Surgeons, New York, in 1940 and entered the service Feb. 22, 1943.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Station Hospital, Camp Claiborne, Alexandria, La.: Evaluation of Cardiac Disease, Dr. Willard With, February 26; Psychosomatic Medicine, Dr. Theodore Watters, February 26; Internal Derangement of the Knee, Lieut. Col. Samuel Terhune, February 26; Amputations, Dr. Rawley Penick, February 26.

U. S. Naval Hospital and LaGarde General Hospital, New Orleans (joint meeting): Internal and External Red Blood Cell Therapy, Dr. Walter Davenport, March 7; Psychosomatic Diagnosis in the Army, Major H. H. Leet and Major Paul Rosenfels, March 7; Radiation Therapy of Tumors, Dr. Manuel Garcia, March 7; Carcinoma of the Colon, Dr. James Rives, March 7.

Station Hospital, Rosecrans Field, St. Joseph, Mo.: Gastrointestinal Diseases, Dr. R. C. Davis, March 8; X-Ray Diagnosis, Dr. Ira H. Lockwood, March 8.

Station Hospital, Camp Stoneman, Pittsburg, Calif.: New Methods of Treatment of Heart Disease, Dr. Francis Chamberlain, March 3.

Vaughan General Hospital, Hines, Ill.: Diagnostic Studies on Status Anginosus, Dr. Chauncey C. Maher, February 21.

A. A. F. Regional Hospital, March Field, Riverside, Calif.: Helminth Infections Common to the Orient, Dr. John Kessell, February 20.

Torney General Hospital, Palm Springs, Calif.: Internal Derangements of the Knee, Dr. John Wilson, February 20.

Station Hospital, Camp Cook, Calif. (afternoon meeting): Some Fundamental Considerations for the Understanding of Psychiatry, Dr. Glen E. Meyers and Comdr. Walter Rapaport, February 21.

Hoff General Hospital, Santa Barbara, Calif.: Some Fundamental Considerations for the Understanding of Psychiatry, Dr. Glen E. Meyers and Comdr. Walter Rapaport, February 21.

U. S. Naval Hospital, Camp Pendleton, Oceanside, Calif.: Some Ideas on the Diagnosis, Prognosis and Treatment of Cardiovascular Diseases, Dr. William D. Stroud, February 20.

U. S. Naval Hospital, Corona, Calif.: Some Ideas on the Diagnosis, Prognosis and Treatment of Cardiovascular Diseases, Dr. William D. Stroud, February 23.

U. S. Naval Air Training Station, San Diego, Calif.: Surgery of the Traumatic Abdomen, Comdr. Gaylord Bates and Dr. C. E. Phillips, February 23.

Birmingham General Hospital, Van Nuys, Calif.: Thoracic Surgery, Dr. John Jones and Lieut. Comdr. J. E. Dailey, February 28.

Vaughan General Hospital, Hines, Ill.: Neurocirculatory Asthenia, 1st Lieut. Lamont Schweiger, February 19; Bronchial Asthma, Capt. William Horwitz, February 20; Blood Dys-

crasias, Major R. N. Tindall, February 22; X-Ray Conference, Major V. Graham, February 22; Peptic Ulcer, Lieut. V. J. LoPiccolo, February 23; Peripheral Vascular Disease, Lieut. Lamont Schweiger, February 26; Pleurisy, Capt. William Horwitz, February 27.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in *THE JOURNAL*, February 10, page 337)

CALIFORNIA

Mount Zion Hospital, San Francisco. Capacity, 193; admissions, 5,333. Dr. J. A. Katzive, Director (resident—roentgenology, disqualified for military service).

GEORGIA

Grady Memorial Hospital, Atlanta. Capacity, 720; admissions, 14,067. Mr. Frank Wilson, Superintendent (residents—medicine, surgery, obstetrics-gynecology; women, or men disqualified for military service). St. Joseph's Infirmary, Atlanta. Capacity, 158; admissions, 5,827. Sister M. Cornile, Superintendent (interns and residents disqualified for military service or applicants from Latin American schools).

ILLINOIS

Hospital of St. Anthony de Padua, Chicago. Capacity, 245; admissions, 6,563. Sister M. Johanne, Superintendent (interns).

IOWA

Iowa Lutheran Hospital, Des Moines. Capacity, 155; admissions, 4,564. Miss Clara Hendrickson, Superintendent (2 interns, July 1).

MISSOURI

Jewish Hospital, St. Louis. Capacity, 303; admissions, 6,704. Miss Florence King, Administrator (resident—surgery, obstetrics-gynecology, disqualified for military service). St. Louis City Hospital, St. Louis. Capacity, 1,104; admissions, 14,693. Dr. Leo J. Wade, Medical Director (3 interns, July 1).

NEW YORK

St. John's Riverside Hospital, Yonkers. Capacity, 220; admissions, 4,429. Mr. S. Chester Fazio, Superintendent (interns).

OREGON

St. Vincent's Hospital, Portland. Capacity, 425; admissions, 10,739. Sister Rose Imelda, R.N., Superintendent (residents—pathology, radiology, disqualified for military service).

RHODE ISLAND

Memorial Hospital, Pawtucket. Capacity, 202; admissions, 4,891. Mr. Walter E. Wright, Superintendent (interns, July 1).

WISCONSIN

Evangelical Deaconess Hospital, Milwaukee. Capacity, 176; admissions, 5,465. Rev. J. P. Meyer, Superintendent (interns).

ORGANIZATION SECTION

HEALTH INSURANCE LEGISLATION IN CALIFORNIA

Analysis of Health Insurance Proposals Before the 1945 California Legislature Prepared by the California Medical Association

Introductory Note.—There are at least thirteen bills before the 1945 legislature on the subjects of state medicine, compulsory health insurance and voluntary health insurance. (This analysis covers bills introduced before Jan. 27, 1945.)

I. COMPULSORY TAX INCREASE BILLS

A.—A. B. 449. Sponsor, the C. I. O. Major features:

1. *Administration.*—Creates new bureau (California Health Insurance Commission) with power to manage and regulate the compulsory health plan. California Health Insurance Commission to consist of nine persons appointed by governor, two from labor, two from management, two from agriculture, one from the medical profession, one full time professor in a medical school, and one from the general public (practicing physicians have one member out of nine). An executive director (who must not be a doctor or dentist) to have full power to manage the day by day operations, his salary to be \$15,000 a year. A medical director to be appointed (salary \$12,000 a year) but his powers, if any, are not specified.

A medical advisory council (two M.D.s, one osteopath, one dentist, one professor, one hospital manager, one pharmacist, a director of public health and one representative of "group practice of medicine") to be appointed by governor. Its powers limited to "advising" the medical director concerning professional and hospital standards of service.

The state to be divided into "areas," each area to have a medical director and an area medical council with power to "advise" on professional matters. The commission may establish "appeal bodies" to hear and determine all disputes subject to final appeal to the commission.

2. *Financing.*—Costs are financed by (a) a payroll tax of 1.5 per cent on employers and 1.5 per cent on employees, (b) appropriations from general taxes (for administration expenses) and (c) payments from counties, etc., to cover cost of indigent care. Political subdivisions must pay such amounts as the commission fixes, but not more than 3 per cent of average wages.

3. *Persons Covered.*—All employees who are now subject to the Unemployment Insurance Act, their wives and children under 18; also all indigents (including old age pensioners); also all state and county employees, their wives and children under 18.

4. *Benefits.*—Medical care, as follows: (a) "general practitioner" services including "preventive," diagnostic and therapeutic treatment and care and physical examinations, (b) "special medical care," i. e., services requiring unusual professional skill or experience by "a legally qualified physician or dentist who is professionally capable of rendering such service" (N. B. Presumably, the Medical Director decides what doctors are specialists and in what specialties), (c) laboratory services including x-ray, clinical laboratory studies and physical therapy, (d) hospital care up to twenty-one days, and (e) dental and nursing care to the extent the Commission finds feasible.

5. *Eligible Purveyors of Benefits.*—(a) All M.D.s, (b) all osteopathic physicians and surgeons, (c) all dentists, (d) such hospitals as are approved by the Commission, (e) all group clinics composed of M.D.s, and (f) all medical school faculty members.

6. *Method of Paying for Benefits.*—All "general practitioner" services are paid on a capitation basis (i. e., each person selects a doctor and the doctor is then paid x dollars a year for each person selecting him, irrespective of the work, if any, done in such year). "Specialist" services and laboratory services will

be paid on a fee schedule. The fee schedule need not be uniform throughout the state.

7. *Effective Dates.*—(a) tax payments, July 1, 1945; (b) benefits, July 1, 1945.

8. *Exemptions.*—None.

B.—A. B. 800. Sponsor, Governor Warren. Major features:

1. *Administration.*—Creates a new state bureau, the California Health Service Authority, with power to operate, manage and regulate a compulsory health insurance plan, subject to the right of the governor to veto or suspend acts of the Authority, the Authority to consist of eleven members and a manager, all appointed by the governor. The eleven members of the Authority shall include three persons from management, three from labor, two members of the medical profession, one physician experienced in hospital management, one dentist and the director of public health. The executive head of the Authority is the manager (salary \$12,000 a year), who is not required to be a physician. The manager is directed to administer the act and to employ such personnel as may be necessary.

2. *Financing.*—Costs are financed by (a) a payroll tax of 1.5 per cent on employers and 1.5 per cent on employees and (b) such amount from the general funds of the state as may be necessary. (Bill states that "the faith and credit of the state are hereby pledged to assure the operation of the . . . system until . . . June 30, 1949.")

3. *Persons Covered.*—All employees who are now subject to the Unemployment Insurance Act, their wives and children under 18; also included are all state, county and municipal employees and their wives and children under 18.

4. *Benefits.*—Medical care as follows: "general practitioner" services including "preventive, diagnostic, therapeutic or other medical treatment or care"; "specialist" services in addition to those of the general practitioner, laboratory and x-ray services, hospital care up to twenty-one days, drugs and medicines, dental services "for the extraction of teeth and for the treatment of acute infections of the teeth, gums and alveolar processes and the bone adjacent thereto, or fractures of the jaws." Additional services may be provided by the Authority from time to time.

5. *Eligible Purveyors of Benefits.*—(a) All M.D.s, (b) all osteopathic physicians and surgeons, (c) all dentists, (d) all optometrists and (e) such hospitals as are approved by the Authority and meet the standards prescribed by the Authority.

6. *Method of Paying for Benefits.*—All services of doctors of medicine, osteopaths, dentists and optometrists will be paid for in accordance with a fee schedule adopted by the Authority. One section of the bill guarantees each person covered the right of free choice from among such physicians, dentists and optometrists as register for services under the act. The Authority may prescribe any fee schedule that it desires, and the fees need not be uniform throughout the state.

7. *Effective Dates.*—(a) Tax payments commence July 1, 1946, (b) benefits commence Jan. 1, 1947. It is provided, however, that the governor may delay the effective dates for not more than one year if the United States is still at war on April 1, 1946; also, if the bill should pass the legislature and be subject to a referendum, the effective dates are automatically postponed for one year.

8. *Exemptions.*—(a) Religious: All people who depend for healing on prayer are exempt both from the benefits and from the payroll taxes (the employer of a religious objector must still pay his 1.5 per cent).

(b) *Employees leaving the state:* Any employee who leaves the state and has paid into the fund an amount less than sufficient to make him eligible for benefits (the minimum is a wage of \$300 a quarter for six months) is entitled to a refund of all taxes paid. (N. B. This is a most amazing principle for a pooled fund insurance scheme.)

(c) *Employer-operated medical plans:* Industrial medical plans owned and operated by an employer may be exempted from both the benefits and the tax by contracting with the manager of the Authority to continue such industrial plan in existence.

(d) *Railroad employees:* Both railroad and maritime employees are exempted from the definition of the term "employment" and therefore apparently are not entitled to any benefits under the bill.

9. *Miscellaneous.*—(a) *Employee Health Plans:* It is made a misdemeanor for any employer to require membership in any health plan as a condition of employment.

(b) *Control over Beneficial Standards:* The bill permits California Health Service Authority to expel any registered physician who rebates fees, seriously neglects the welfare of the patient or intentionally violates any rule or regulation of the Authority.

(c) *Penalties:* It is a misdemeanor to violate any provision of the act or of the regulations thereunder or to fail to make full reports to the Authority.

C.—A. B. 1414. Sponsor not known, but the bill is identical with Governor Olson's 1939 compulsory health insurance bill. Major features:

1. *Administration.*—Adds a Division of Medical Service to the Department of Employment. Provides for a medical director as the chief of the division, the medical director being charged with the administration of the professional phases of the plan. Otherwise the present California Unemployment Commission is given full power to administer the so-called "social insurance benefits." The bill is in the form of an amendment to the Unemployment Relief Act and hence utilizes the existence of the Unemployment Commission as the administrative body.

2. *Financing.*—Proposes a 1 per cent tax on employers and a 1 per cent tax on employees and provides for a contribution from the general funds of the state equal to 1 per cent of all wages paid to the state.

3. *Persons Covered.*—All employees now subject to the Unemployment Insurance Act and not now earning more than \$3,000 a year and their wives and children under 21.

4. *Benefits.*—Medical benefits include the services of general practitioners, the services of specialists, laboratory and x-ray services, hospitalization, nursing services, drugs and medicines, and dental services as follows: extraction of teeth, treatment of osteomyelitis of the jaw, trench mouth and jaw fractures, and optometric services. In addition to the medical benefits the bill also provides for cash sickness payments to employed persons when ill or injured, these payments to be made out of the Unemployment Fund and to be equal in amount to the present unemployment benefits.

5. *Eligible Purveyors of Benefits.*—All M.D.s, all osteopathic physicians and surgeons, licensed optometrists, licensed dentists and approved hospitals.

6. *Method of Paying for Benefits.*—General practitioners to be paid on the capitation system; specialists, dentists, optometrists, x-ray and laboratory services and hospitalization to be paid under a fee schedule, the fee schedule to be fixed by the California Employment Stabilization Commission and the medical director. Various provisions of the bill permit the state to contract with closed panel group clinics for the purpose of permitting such clinics to render all of the medical services provided in the bill on a fixed amount per annum, closed panel group clinics being expressly incorporated by various sections of the bill.

D.—S. B. 218. Sponsor, the California Farm Bureau. Major features:

This bill relates only to county hospitals. Its purpose is to open all county hospitals to all residents of each county, regardless of income. The bill divides all citizens into three classes:

A, indigents; B, poor but able to pay some costs; C, able to pay full costs of medical care and hospitalization. Classification into A, B or C is determined by reference to each person's income, amount of property owned and wealth of near relatives legally liable for his or her support.

Those in class A are entitled to hospitalization and medical care at the expense of the county.

Those in class B are entitled to medical care and hospitalization at the expense of the county but are required to contribute to the county such portion of such expense as they are able to pay.

Those in class C are entitled to hospitalization in the county hospital but must pay the full cost of such hospitalization. People in class C are not entitled to any medical care from the county but are privileged to have their own physicians or dentists treat them in the county hospital while hospitalized.

As to people in class C, physicians and dentists are permitted to charge private fees. As to those in class A and class B, medical care is rendered by the county hospital staff and no charge may be made.

All costs of operating the county hospital constitute a charge against county taxes. The bill also provides that in each county there shall be a Board of Public Welfare of seven persons, two from agriculture, two from medicine, one from osteopathy and two from business and labor groups. Classification of patients admitted into the county hospital into A, B or C would be made by a medical social service investigating agency acting under the jurisdiction of the Board of Supervisors, provided that any person not satisfied with the medical social service classification may appeal to the county Board of Public Welfare.

In substance, this bill would change county hospitals from charity institutions to a combination charity hospital and private hospital.

II. VOLUNTARY BILLS

A.—A. B. 1200. Sponsor, the California Medical Association. Major features:

1. *Administration.*—As this bill proposes aid and assistance to existing voluntary nonprofit plans, there is no new bureau created and no additional governmental employees contemplated. The bill is in the form of an amendment to the Unemployment Insurance Act, and the little administration that is necessary will be done by the existing Employment Stabilization Commission.

2. *Financing.*—Again, as this is a voluntary plan, no new taxes are contemplated. The existing tax structure of the Unemployment Insurance Act, which has proved to be more than necessary for unemployment relief, will be utilized under this bill for assisting in spreading the cost of medical care.

3. *Benefits.*—(a) Voluntary nonprofit medical and hospital plans: To encourage people to enroll in these plans, of which there are many in the state, the bill cuts the employee's 1 per cent payroll contribution to the Unemployment Fund in half; thus an employee who enrolls himself and his family in a nonprofit medical and hospital plan would thereafter be taxed $\frac{1}{2}$ of 1 per cent instead of 1 per cent by the state unemployment act. If he earns \$200 a month, this means a tax saving of \$1, which is automatically applied against his monthly dues to the voluntary plan. In the average case this would amount to about one fourth to one third of the total dues charged by existing voluntary plans. This can be done within the existing tax structure. Using 1944 as an example, if this bill had been in effect the $\frac{1}{2}$ of 1 per cent reduction in employees' unemployment contributions would have cost the fund about \$25,000,000. In all years since 1936 the costs of the Unemployment Fund have been sufficiently under the tax receipts so that a reduction of $\frac{1}{2}$ of 1 per cent could have been made without jeopardizing the Unemployment Fund. In fact, California and three other states are the only ones who tax the employee anything for unemployment relief, so that we have in this state the full 1 per cent employees' tax over and above the comparable resources of the unemployment funds in forty-four of the states. This bill proposes to make some use of this existing excessive tax and to allow the people to get some benefit from it.

(b) Allows employers to make payroll deductions for all employees for payment of dues or premiums for approved hospitals.

pital, medical or surgical prepayment plans. Exceptions under this rule would be made for employees who state in writing their objections to inclusion in such plans. This feature follows the election procedure of the National Labor Relations Act, providing that the majority of employees may bind all employees in joining approved nonprofit plans.

(c) Provides that regular unemployment benefits will be paid to employees who are hospitalized for illness and who are not covered for hospitalization by an approved nonprofit plan. A preliminary actuarial study indicates that this provision of the bill will cost the fund not more than \$2,500,000 a year, based on the incidents of hospitalization and the number of people covered. Actually it will probably cost the fund less than \$2,500,000, because most employees will join voluntary plans to get the tax reduction provided in another part of the bill, and as to such employees sickness benefits are not payable as they are already covered; \$2,500,000 is therefore the maximum cost. In 1944 the unemployment tax collections totaled about \$170,000,000, so that \$2,500,000 is less than 2 per cent of the annual funds available.

4. *Approved Voluntary Plans.*—The bill provides the following types of voluntary plans approved for the purpose of qualifying persons who enroll for the benefits that have been set forth: (a) California Physicians' Service, or any comparable plan formed by the osteopathic physicians and surgeons or the dentists; (b) The Blue Cross plans, i. e., nonprofit hospitalization plans operated by the hospitals, and (c) all insurance company medical, surgical and hospital reimbursement policies.

Each and all of the foregoing types of plan qualify, and people who join them will, under the bill, be entitled to the tax reduction as described. In order to prevent fraudulent plans from springing into existence it was necessary to describe the type of voluntary plan that meets with the state's approval. Descriptions used in the bill are sufficiently broad to cover all types of plan that provide free choice of physician and which give to the public reasonable value for their money paid.

5. *Miscellaneous.*—The incentives that are given to existing private enterprise by this bill will result, if the bill becomes law, in the bulk of the low and middle income population of the state enrolling in voluntary plans. This can all be accomplished without increasing the tax structure and further penalizing California business and industry. At the same time, because private enterprise always operates more efficiently than governmental monopolistic bureaus, the people will get more value for each dollar paid than they ever will through a compulsory plan. B.—S. B. 219. Sponsor, the California Farm Bureau. Major features:

The purpose of this bill is to remove all doubts as to the legality of closed panel group or contract medical practice. Under the bill, any group of physicians or any corporation may enter into contracts with subscribers for the furnishing of health services on a prepayment basis if such group of physicians or corporations has first obtained from the State Department of Public Health a license authorizing it to transact a prepayment health service plan. The bill prohibits operations by any prepayment plan that does not qualify for a license from the Department of Public Health. There is no requirement in the bill that health service associations offer free choice of physician or hospital; on the contrary, the bill contemplates closed panel or salaried medical staffs to render services to the people who join health service associations. It is provided that associations formed under the bill shall not be subject to the insurance laws of the state. It is also provided that health service associations may be formed either by members of the general public for the purpose of contracting with physicians or by groups of physicians for the purpose of contracting with members of the public.

It is not clear whether the bill, if enacted into law, would affect California Physicians' Service and existing insurance company reimbursement contracts. It is clear that the bill, if enacted, will legalize operations of closed panel clinics such as Ross-Loos, Chartres-Martin, Stowe-Lipsett and Fred W. Callison and Staff.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Change in Status.—H. R. 1984 has passed the House of Representatives, a bill making appropriations for the executive office and sundry independent executive bureaus, boards, commissions and offices, for the fiscal year ending June 30, 1946. This bill, among other things, proposes an appropriation of \$2,707,119,250 for the Veterans Administration, representing an increase over appropriations made for 1945 of \$1,436,707,185. Of the total proposed to be appropriated in 1946, \$227,675,000 will be used for the administration, medical, hospital and domiciliary services and \$84,500,000 for new hospital and domiciliary facilities.

Bills Introduced.—H. R. 1415, introduced by Representative Angell, Oregon, proposes an appropriation of \$11,580,000 annually to provide for the education of children who are crippled, blind, partially seeing, deaf, hard of hearing, defective in speech, cardiopathic, tuberculous or otherwise physically handicapped and who for their education require an expenditure of money in excess of the cost of educating physically normal children. H. R. 1923, introduced by Representative Morrison, Louisiana, proposes to eliminate financial inability to defray expenses of hospital treatment or domiciliary care as a prerequisite to a veteran obtaining such treatment or care in a Veterans Administration facility. H. R. 1998, introduced by Representative Hoch, Pennsylvania, proposes to establish a chiropody corps in the Medical Corps of the Army and to establish a chiropody reserve corps. H. R. 1999, introduced by Representative King, California, proposes to establish a joint committee to select a suitable medal or award to be bestowed on members of selective service local boards. H. R. 2020, introduced by Representative Voorhis, California, proposes to amend title X of the Social Security Act to provide additional benefits for the blind. H. R. 2045, introduced by Representative Hartley, New Jersey, proposes an appropriation of \$25,000,000 for the fiscal year beginning July 1, 1945 to aid the several states and territories in providing a program of physical fitness activities, to be promoted by the United States Commission for the Promotion of Physical Fitness to be created by the bill. S. 436, introduced by Senator Thomas, Oklahoma, proposes to equalize state old age assistance payments and to provide burial allowances under title I of the Social Security Act.

DISTRICT OF COLUMBIA

Bill Introduced.—H. R. 1997, introduced by Representative Hebert, Louisiana, proposes to regulate the practice of optometry in the District of Columbia, defined as "the measurement and correction of refractive and muscular errors of the eye by any method not including the use of drugs and not including surgical procedures such as cutting or actual manipulation of the eyeball, but including the use of optical appliances for diagnosis or correction of such refractive and muscular errors."

STATE LEGISLATION

Arizona

Bills Introduced.—S. 43 and S. 68, to amend the basic science act, propose to authorize the issuance without examination of a certificate of registration in the basic sciences to any person presenting evidence satisfactory to the board of basic science examiners that he has received a certificate of registration, or its equivalent, in the basic sciences in a state in which the requirements therefor are at least equal to those in force in Arizona at that time. S. 55 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a physician's certificate, based on standard serologic tests for venereal disease, that the party either is not infected with venereal disease or, if so infected, is not in a state which may become communicable to the marital partner.

Arkansas

Bill Introduced.—H. 130 proposes to require any person who undertakes to care for a pregnant woman to take or cause to be taken a sample of her venous blood at the time of first examination and to subject that sample to an approved serologic test for syphilis.

California

Bills Introduced.—S. 500 proposes a system of compulsory state health insurance. S. 653 proposes to direct the state department of public health to develop a program for the collection, processing and distribution of human whole blood, blood plasma and products derived from human blood. S. 699 proposes to authorize the admittance of pay patients to county hospitals. A. 1089, to amend the medical practice act, proposes that, of the ten members of the board of medical examiners, two be drugless licentiates and two be chiroprodists.

Colorado

Bills Introduced.—S. 303 proposes to authorize the sexual sterilization of certain insane, feeble-minded or epileptic inmates of state institutions. S. 457 proposes to authorize licensed chiropractors to execute death certificates.

Georgia

Bill Introduced.—H. 272 proposes to enact a separate naturopathic practice act and to create an independent board of naturopathic examiners to examine and license applicants for licenses to practice naturopathy as defined in the bill.

Idaho

Bill Introduced.—S. 8 proposes to enact a separate naturopathic practice act and to create an independent board of naturopathic examiners to examine and license applicants for licenses to practice naturopathy as defined in the bill.

Indiana

Bills Introduced.—S. J. R. 7 seeks to create a joint senate and house committee to ascertain if the Indiana Medical School cannot graduate each year more students. S. 181 proposes to enact a separate chiropractic practice act and to create an independent board of examiners to examine and license applicants for licenses to practice chiropractic, which is defined as "a system of locating and correcting any interference with normal nerve transmission and expression by the employment of drugless methods."

Kansas

Bills Introduced.—H. 90 proposes to authorize the formation and operation of nonprofit corporations to operate medical service plans. H. 95 proposes a complete revision of the medical practice act. Among other things, it proposes to grant to licensed osteopaths the right to be given by the board of medical examiners the same examination as that given nonsectarian applicants and if successful in passing those examinations to be granted licenses to practice without restriction.

Maine

Bill Introduced.—H. 648, to amend the workmen's compensation act, proposes among other things to make compensable "a personal injury, disease or occupational disability arising out of and in the course of his employment."

Massachusetts

Bills Introduced.—H. 757 proposes that no persons be required to submit to vaccination or inoculation of any kind or to subject their minor children or wards to any medication, vaccination or inoculation against their will as a condition precedent to admission to or attendance at any public school or other institution. H. 756 proposes to prohibit a physician performing any surgical operation in a hospital supported in whole or in part by public funds or contributions to charge more than \$150 for his services in connection with that operation. H. 755, to amend the medical practice act, proposes to repeal chapter 247 of the laws of 1936, which in effect raised the educational requirements by limiting eligible applicants for licensure after examination to graduates of legally chartered medical colleges approved by an approving authority set up by the act.

Minnesota

Bill Introduced.—S. 308 proposes to authorize the organization of nonprofit corporations to operate medical service plans.

Montana

Bills Introduced.—H. 188 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a physician's certificate, based on physical examination and standard serologic tests, that the party either is not infected with syphilis or, if so infected, is not in a stage of the disease which is or may become communicable to the prospective marital partner. H. 189 proposes to require a physician or other person attending a pregnant woman for conditions relating to pregnancy to take or cause to be taken a sample of her blood for submission to an approved laboratory for a standard serologic test for syphilis.

New Jersey

Bills Introduced.—S. 11 proposes to authorize a judge in a criminal cause to order any person appearing before him, if he has reasonable grounds for suspecting the presence of syphilis in the party, to submit to examination for the discovery of syphilis and to require the party to submit to treatment therefor. S. 12 proposes that any migrant laborer who cannot produce satisfactory evidence of examination for venereal disease having been performed on him within ninety days prior to entry to New Jersey to submit within thirty days after such entry to such examination as may be prescribed by the state department of health. S. 27 proposes to enact a system of cash sickness compensation payable to persons unable by reason of sickness to work.

New Mexico

Bill Introduced.—H. 81 proposes to enact a separate naturopathic practice act and to create an independent board to examine and license applicants for licenses to practice naturopathy. Such applicants are to be exempt from the provisions of the state basic science act.

North Dakota

Bills Introduced.—H. 90 proposes to prohibit the operation of a hospital without a license from the state department of health. S. 115 proposes to establish a North Dakota state medical center at the University of North Dakota, the purpose of which is to provide facilities for the coordination, improvement, expansion and unification of health and welfare activities of the state and its agencies and political subdivisions and private medical practitioners.

Ohio

Bill Introduced.—H. 62 proposes so to amend the medical practice act as to exempt from its provisions "ministering to human ills through prayer or spiritual means alone in accordance with the tenets or teachings of any religious denomination by a member in good standing of such denomination."

Oklahoma

Bill Introduced.—S. 54 proposes to enact a venereal disease control law under the provisions of which any physician diagnosing or treating a case of venereal disease is to be required to report the facts to stated health authorities.

South Carolina

Bill Introduced.—S. 101 proposes to require every physician attending a pregnant woman for a condition relating to pregnancy to take or cause to be taken a sample of her blood at the time of first examination and to submit that sample to an approved laboratory for a standard serologic test for syphilis.

Tennessee

Bills Introduced.—S. 239 and H. 340, to amend the naturopathic practice act, proposes that nothing in that act shall permit a naturopath to use "powerful and dangerous drugs, such as narcotics, anesthetics, sedatives, sulfa drugs and other toxic drugs and biologicals, or powerful physical agents, such as x-ray therapy."

Texas

Bills Introduced.—H. 29, to amend the medical practice act, proposes that a chiropractor engaged in palpating, analyzing and adjusting the articulations of the human spinal column by

hand only shall not be regarded as practicing medicine within the meaning of the medical practice act. H. 82 proposes to enact a separate naturopathic practice act and to create an independent board of examiners to examine and license applicants for licenses to practice naturopathy. H. 93 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a physician's certificate, based on standard serologic tests for venereal diseases, that the party either is not infected with a venereal disease or, if so infected, is not in a state which may become communicable to the marital partner. H. 97, to amend the medical practice act, proposes that nothing in the act shall be construed so as to affect "naturopathic physicians, duly licensed under the laws of this state, who confine their practice to naturopathy as defined by statutes." H. 127 proposes to prohibit the operation of a convalescent home without a license from the state department of public health. S. 57 proposes to enact a separate chiropractic practice act and to create an independent board of chiropractic examiners to examine and license applicants for licenses to practice chiropractic. Chiropractic is defined as "the employment of objective or subjective means, without the use of drugs or surgery, for the purpose of ascertaining the alignment of the vertebrae of the human spine, and the practice of adjusting the vertebrae by hand to correct or remedy any defect or abnormal condition of alignment." S. 65 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a physician's certificate, based on examination and serologic test, that the party is not infected with syphilis or, if so infected, is not in a stage of that disease which is or may become communicable. S. 66 proposes to require a physician attending a pregnant woman to take or cause to be taken a specimen of her blood for a standard approved serologic test for syphilis.

Utah

Bill Passed.—H. 28 passed the house, January 22, proposing to amend the law conditioning the issuance of a license to marry on the presentation by each party to the proposed marriage of a certificate of a physician licensed in Utah that the party is free from stated venereal disease. The bill proposes that "any certificate form which has been approved by the proper authority in any state requiring premarital examinations for venereal diseases shall be accepted in this state." H. 77 proposes to prohibit an employer, as a condition of employment, from requiring any person applying for employment to obtain a physical examination unless the employer pays all costs and expenses incident to the examination.

Bill Introduced.—S. 115 proposes to enact what appears to be the uniform narcotic drug act.

Vermont

Bill Introduced.—S. 9, to amend the workmen's compensation act, proposes to require an employer to furnish an injured workman reasonable surgical, medical and nursing services and supplies during a period of sixty consecutive days commencing when medical attention is first given outside a hospital but not later than ninety days from the date of the injury and not to exceed \$75 in amount. The present law limits the time to fourteen days of disability and the amount to \$50, exclusive of hospital charges.

Washington

Bills Introduced.—S. 29 proposes to enact a separate act regulating the practice of massotherapy and to create a board of examiners in massotherapy. Massotherapy is defined as "the method, art or science of treating the human body for hygienic or remedial purposes to maintain health and to establish a normal condition of the body, and shall include all massage manipulations, passive and active remedial gymnastics and relaxing movements and manipulations with the hands or with any other agency or instrumentality designed to accomplish massage manipulations or gymnastics, or by mechanical gymnastics to promote physiological action to bring about a normal condition of health and restore bodily functions to a normal condition."

S. 77 proposes after Jan. 1, 1946 to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a certificate of a licensed physician, based on a standard serologic test made not more than thirty days prior to the issuance of the license, that the party either is not infected with syphilis or, if so infected, is not in a stage of the disease that is or may become communicable to the marital partner. H. 47 proposes to authorize the establishment of public hospital districts to operate hospital facilities to supply hospital service for district residents. The medical management of such hospitals is to be subject to the approval of the medical staffs therein, and all such hospitals are to be operated in compliance with standards set by the Council on Medical Education and Hospitals of the American Medical Association. H. 60 proposes in effect to exempt applicants for licenses to practice chiropractic from the provisions of the basic science act. H. 81 proposes that the law prohibiting the retail sale of certain hypnotic and sulfa drugs except on a prescription of a licensed physician, dentist or veterinarian shall not apply "to the sale of sulfa drugs and their compounds for external or topical application when so marked and labeled or to the sale of veterinary sulfa products and their compounds when so marked and labeled but only after each of said drugs or products has been approved as being safe for use without medical supervision by regulation of the Board of Pharmacy of this state."

West Virginia

Bill Introduced.—H. 9 proposes to require every pregnant woman to have a sample of her blood taken and submitted to the West Virginia state hygienic laboratory or other approved laboratory for the performance of a standard serologic test for syphilis. Every physician or other person engaged in attendance on a pregnant woman shall acquaint her with the requirements noted and take or cause to be taken a specimen of her blood for submission to a laboratory.

Wisconsin

Bills Introduced.—A. 49, to amend the narcotic drug act, proposes so to amend the "narcotic drug" act as to include isoniphecaïne. S. 6, to amend the medical practice act, proposes to prohibit a person licensed to practice any form of the healing art to practice under any name other than that under which he was originally licensed in any instance in which practicing under the changed name operates to compete unfairly with another practitioner, to mislead the public as to identity, or otherwise to result in detriment to the profession or the public.

Woman's Auxiliary

North Carolina

The Woman's Auxiliary to the North Carolina Medical Society is stressing support of the Medical and Surgical Relief Committee of America. Mrs. John T. Saunders, president, suggested that kits be given in memory of persons lost in the service. The auxiliary is still working on kits for the amphibious forces.

Pennsylvania

Seventy-five members attended the first meeting of the Woman's Auxiliary to the Philadelphia County Medical Society, October 10. Dr. Charles L. Brown, president of the Philadelphia County Medical Society, and Mr. Don Rose, columnist for the Philadelphia *Evening Bulletin*, were guest speakers.

Wisconsin

The Woman's Auxiliary to the Dodge County Medical Society sent Christmas gifts to all of the Dodge County Medical Society members in the armed forces.

Dr. Carl A. Moyer of the University of Michigan Medical School, Ann Arbor, recently addressed the members of the Woman's Auxiliary to the Milwaukee County Medical Society on "The Dog in Modern Medicine."

Washington Letter

(From a Special Correspondent)

Feb. 12, 1945.

Appeal for Nurses "Drains" Veterans' Hospitals

The current drive for nurses for the armed forces has had an almost disastrous effect on veterans' hospitals, George E. Ijans, assistant administrator of the Veterans Administration, advised the House Military Affairs Committee. Nurses have "left in droves" to join up, and as a result veterans' hospitals need 1,000 more nurses immediately and 4,000 within the next two years. "We have asked Secretary of War Stimson three times to commission our nurses so they will stay with us," said Mr. Ijans. World War II veterans are pouring into veterans' hospitals. The present patient load includes 43,598 World War I patients and 15,772 World War II patients; and 2,897 more wounded men were turned over from Army and Navy hospitals last month. Tuberculosis and psychiatric beds are already full and the Veterans Administration is taking over several more hospitals from the Army for psychiatric patients. All tuberculosis and psychiatric wards are already full. Mr. Ijans said he favored a draft of dietitians and technicians with nurses. He admitted that little effort had been made to utilize a pool of 9,000 registered Negro nurses.

Capital May Get Clinic for Chronic Alcoholic Addicts

Dr. Michael Miller, St. Elizabeths Hospital psychiatrist and expert on treatment for alcoholic addicts, has volunteered to serve as chief of a proposed experimental clinic for alcoholic addicts in Washington, for which a bill is to be submitted to Congress. Representative John L. McMillan, Democrat of South Carolina, will sponsor the bill, which, according to Charles V. Morris, secretary of the corrections division of the Council of Social Agencies, will be drawn by five of its members. Alternative projects discussed by the council here were (1) an experimental clinic in the Capital staffed with volunteer workers, (2) promotion of legislation to establish the clinic as a part of the District government or as a separate agency and (3) a request for funds to expand the mental hygiene clinic already authorized under the District Health Department.

Industrial Accidents Injure 2,225,000 Persons

Secretary of Labor Frances Perkins estimated today that two and a quarter million persons were disabled during 1944 through industrial injuries. This represents an upward trend in work injuries which started in 1938, but the 1944 total was below that for 1943. Field safety experts of the department, Miss Perkins said, had brought a working knowledge of industrial safety technics to nearly 30,000 war production plants, which she said indicated that adequate instruction and supervision of workers can reduce accidents. The 1944 record is serious, she added, as it involved an actual loss in working time of more than forty-three and a half million work days, equivalent to full annual employment for 145,000 workers. Only two of the major industry groups had increases in 1944 over 1943, trade and railroads, although in neither case was the increase pronounced.

Alfaro Heads UNRRA Mission in Caribbean Area

Herbert H. Lehman, director general of the United Nations Relief and Rehabilitation Administration, announces the appointment of Dr. Ricardo J. Alfaro, former president of Panama, to head an UNRRA mission for eight member governments in the Caribbean area. The mission will visit Panama, Costa Rica, Nicaragua, Honduras, El Salvador, Guatemala, Haiti and the Dominican Republic. Discussions will be held with the governments of each country on collaboration with UNRRA. The way in which each government can participate fully in the UNRRA program will be considered. Mr. Lehman also announces the appointment of Comdr. R. G. A. Jackson of Australia as senior deputy director general. Commander Jackson, who is expected in Washington soon, was head of the Middle East Supply Center in 1943 and was appointed in 1944 principal assistant to the United Kingdom minister of state in the Middle East.

Red Cross Prepares for Floods in Eastern States

Flood preparedness plans have been completed throughout snow jammed New England and the Middle Atlantic states, according to Basil O'Connor, national chairman of the Red Cross. Disaster representatives have visited all danger points within the past three weeks to confer with Red Cross chapters in threatened valleys. The heaviest snow cover and greatest flood potentiality is said to lie in the Connecticut River valley and also in the valleys of the Allegheny, Monongahela, Conemaugh, Susquehanna, Delaware, Lehigh, Schuylkill and Juniata rivers in Pennsylvania and the upper Hudson, Mohawk, Tonawanda, Chenango and Merrimac rivers in New York and New England. Gradual thawing is now in progress in these areas.

Undulant Fever Cases Show Increase During 1945

The U. S. Public Health Service reports that almost twice as many cases of undulant fever have been reported so far this year as compared with the same period in 1944. The total on February 3 was 354 as against 184 for last year. Reporting of cases of undulant fever is now required in all forty-eight states and the District of Columbia, but 1944 was the first year in which all states reported the disease. Failure of some states to report may have accounted for the lower record for 1943. The U. S. Public Health Service states that "the nation's health is otherwise good, with no major increases in communicable diseases reported."

Social Hygiene Program in Capital Applauded

The Social Hygiene Society of the District of Columbia has been widely applauded for its work. Praise was bestowed in connection with the observance of Social Hygiene Day in Washington. It was emphasized that through its efforts the fight against venereal disease and prostitution had been brought into the open. Better understanding of venereal diseases and better cures have assisted the work of social hygiene workers materially. Greater emphasis is being given to sex education and the building of character. In the District, seriously diseased prostitutes are sent to Washington's new 100 bed rapid treatment center in Gallinger Hospital. Health Officer George H. Ruhland reports that 2,200 patients were treated there last year. Physicians report more cases under treatment than formerly, and the venereal disease clinics are said to be in greater use. The worst peril at this time is regarded as the "victory girls" and amateur pickups, whose promiscuity with men in uniform has added to venereal disease statistics.

Official Notes

RADIO NETWORK BROADCASTS

"Doctors Look Ahead" is both title and theme for the National Broadcasting Company network broadcast by the American Medical Association which began January 6 and will run weekly through June 30 each Saturday at 4 p. m. Eastern War Time (3 p. m. Central War Time, 2 p. m. Mountain War Time and 1 p. m. Pacific War Time). This program, now in its twelfth year, is aired cooperatively by the American Medical Association and the National Broadcasting Company on a sustaining nonprofit basis as an educational feature. This is the tenth consecutive year of dramatization.

The forthcoming subjects are:

February 17. Refrigeration Anesthesia.

February 24. Discharged Soldier.

March 3. Nutrition at Home (Dr. G. K. Anderson).

Local stations sometimes record the program for broadcasting at an hour other than the network schedule. Local papers should be consulted if the program is not heard at the time announced.

The Bureau of Health Education, which directs the program, welcomes comments and suggestions from physicians.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

DISTRICT OF COLUMBIA

Dr. Guthrie Goes to Connecticut.—Dr. Riley Henry Guthrie, assistant superintendent of St. Elizabeths Hospital and professor of clinical psychiatry at Georgetown University School of Medicine, Washington, has resigned to become superintendent of the Norwich (Conn.) State Hospital, effective February 1. Dr. Guthrie graduated at the University of Tennessee College of Medicine, Memphis, in 1921 and was formerly associated with the Boston Psychopathic Hospital.

GEORGIA

Proposed Program to Coordinate Health Activities.—The health panel of the Agricultural and Industrial Development Board of Georgia has submitted a program to coordinate health activities in the state and improve the efficiency of operation. The plan has the approval of the state board of health, the Georgia Hospital Association and the Medical Association of Georgia, and it is hoped that the present legislature will endorse it. It has been recommended that the state be divided into nine districts, each to have a complete medical staff composed of administrator, epidemiologist, venereal disease control officer, tuberculosis control officer and maternal and child hygiene control officer, to be solely responsible for the complete public health program in the district. In addition there would be one sanitary engineer in each office. The recommendations carry certain provisions for the availability of nurses. Under the plan each county board of health would operate under its present powers. The health panel also suggests that the act of 1941, which gave each county the right to create a hospital authority, be made operative in every county, the hospital authority to be responsible for the construction and maintenance of hospitals, clinics and health centers. Certain recommendations have been made for the financial handling of the program, which has been described as definitely the development program for the postwar period in Georgia.

ILLINOIS

Personal.—Dr. Charles D. Nobles has been appointed managing officer of the Anna State Hospital, Anna.—Dr. Margaret M. Scannell has resigned as medical officer with the Illinois Commission for Handicapped Children to enter private practice in the Chicago area, effective January 31.

Change in Health Literature.—Effective with the issue of January 6, the former weekly and biweekly bulletins of the Illinois Department of Public Health will be combined and issued as the Weekly Report of the Division of Communicable Diseases. Tables will be used to indicate the current week's provisional case reports of the more important communicable diseases, both in the state as a whole and in Chicago. The case reports for the same week of last year, and the five year median, when this is of significance, will also be shown for the purpose of comparison.

Kenneth Morse Temporarily Placed in Charge of Industrial Hygiene.—Kenneth M. Morse, engineer in the division, has been appointed temporarily to take charge of the division of industrial hygiene in the Illinois Department of Public Health. The appointment was made necessary by the reactivation of the U. S. Public Health Service commission of Dr. Bruce M. Brown, acting medical director of the division of industrial hygiene, Iowa Department of Health, Des Moines, who has been assigned to immediate duty with the coast guard (THE JOURNAL, January 6, p. 45).

KANSAS

Fred Mayes Returns to Kansas.—Dr. William Fred Mayes, who resigned as director of the division of maternal and child welfare, state board of health, Topeka, to become regional medical consultant to the U. S. Children's Bureau, Washington, D. C., has returned to the state board of health as assistant state health officer and director of local health services (THE JOURNAL, Jan. 15, 1944, p. 180). Dr. Mayes, who previously served with the state board, first as assistant director and later as director of the division of maternal and child welfare, carried on his activities with the Children's

Bureau in seven Southeastern states. The position of director of local health services of the state health department has been vacant since the resignation of Dr. Henry H. Asher to become health officer of Alger and Schoolcraft counties, Mich. (THE JOURNAL, Sept. 18, 1943, p. 158).

MASSACHUSETTS

Putnam Fellowship for Advanced Research Available.—Applications for the Helen Putnam Fellowship for Advanced Research in genetics or mental health should be submitted to Radcliffe College, Cambridge, not later than April 15. The fellowship, which bears the name of the physician who gave the endowment for the award, will pay a stipend of \$1,900 and its tenure will run for a term of eleven months from October 1 with the possibility of a renewal for a similar period. All normal laboratory facilities will be provided to the holder of the fellowship. Each fellow will be assigned room and board (at cost) in one of the Radcliffe graduate houses and will be expected to be in residence during the tenure of the fellowship. No restrictions as to age will be imposed by the committee on award. In general, however, the committee will limit its choice to mature women scholars who have gained their doctorate or who possess equivalent qualifications. All candidates for the fellowship will be required to submit formal proof of their scholarly attainments and productivity. Appointments will be limited to those candidates who can submit a plan of research that is already under way, and proofs of progress may be required by the committee. The creation of the fellowship was announced in THE JOURNAL, Dec. 23, 1944, page 1094. The committee on award, which includes six members of the faculty of Harvard University, and Wilbur K. Jordan, Ph.D., president of Radcliffe College, will announce the appointment to the fellowship on or about May 15. Additional information may be obtained from the Committee on the Helen Putnam Fellowship for Advanced Research, Radcliffe College, Cambridge 38.

MICHIGAN

Clinical Teaching in Internal Medicine.—The department of postgraduate medicine of the University of Michigan Medical School, Ann Arbor, of which Dr. Howard H. Cummings is chairman, has arranged a clinical teaching program every Thursday afternoon beginning March 1 and continuing through May 3 at the University Hospital. Designed to serve practicing physicians, the program will be carried out on ward rounds conducted by two different members of the senior staff of the department of internal medicine and will end with a conference of the entire medical staff in review of recent electrocardiograms. If the course is acceptable and serves the needs of the medical profession, it may be extended throughout the school year.

Raymond Hussey to Organize School of Occupational Health.—Dr. Raymond Hussey, Baltimore, has been returned from active military duty to inactive status in order to become dean, professor of preventive medicine and organizer of the School of Occupational Health at the Wayne University Medical Science Center, Detroit. In developing the program Dr. Hussey announces that the positive aspect of health will be the main consideration in developing the engineering-medical relations for the promotion and maintenance of health through the establishment of employee health programs in all levels of occupation. Dr. Hussey, who, during his period of service with the Army of the United States, organized and directed the activities of the Army Industrial Hygiene Laboratory, graduated at the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1911. In the past his work has included the organization and direction of the medical board for occupational diseases in Maryland. He held the chairmanship of the committee on industrial health of the Medical and Chirurgical Faculty of Maryland and is currently a member of the Council on Industrial Health of the American Medical Association, serving as chairman of its committee on workmen's compensation.

MISSOURI

License Restored.—Dr. Ludwig O. Muench, Washington, was recently granted a restoration of his license to practice medicine in Missouri (THE JOURNAL, June 24, 1944, p. 588).

The Loeb Lecture.—Dr. Alfred Blalock, professor of surgery, Johns Hopkins University School of Medicine, Baltimore, delivered the tenth annual Leo Loeb Lecture in St. Louis, February 13, under the auspices of Mu chapter of Phi Beta Pi Fraternity, Washington University School of Medicine. His subject was "Traumatic Shock."

Forty-Five Year Probation for Narcotic Violation.—Dr. Minor J. Holmes, Kansas City, on Oct. 9, 1944 was placed on probation for a period of forty-five years for violation of the federal narcotic laws. According to the Bureau of Narcotics, Washington, D. C., Dr. Holmes was convicted in the U. S. District Court on Feb. 17, 1944, and on October 10 his sentence of two years was suspended and he was placed on probation for a period of five years. On October 3, according to the Bureau of Narcotics, Dr. Holmes had withdrawn his plea of not guilty and entered a plea of guilty to nine counts of the indictment. October 9 his sentence of five years was suspended and he was placed on probation for a period of forty-five years. Under the terms of the probation it was stipulated that Dr. Holmes should not prescribe or dispense narcotic drugs and should not engage in the practice of medicine.

NEW YORK

Erie Bulletin Changes Face.—The *Bulletin* of the Medical Society of the County of Erie and the Buffalo Academy of Medicine appeared in a larger size with a complete change of format in January. New columns have been added, including one page on the workmen's compensation board. In an editorial comment it was stated that the new bulletin will serve as an instrument of promoting health and welfare as well as a coordinating link to members in service and their civilian confrères.

Graduate Lectures.—The Tompkins County Medical Society will be addressed in Ithaca, February 20, by Dr. Howard B. Slavin, Rochester, on "Penicillin Therapy" and March 20 by Dr. Barton F. Hauenstein, Buffalo, on "Present and Postwar Importance of Malaria." Dr. Percival K. Menzies, Syracuse, will address the Cortland County Medical Society, March 16, on "Treatment of Injuries to the Hands and Feet." Dr. Leo E. Gibson, professor of clinical surgery (urology), Syracuse University College of Medicine, will deliver a graduate lecture before the Cortland County Medical Society, February 16, at the Cortland County Hospital. His subject will be "Infections of the Genitourinary Tract." These lectures are sponsored cooperatively by the state medical society and the state department of health.

Survey to Determine Facilities for Narcotic Care.—The bureau of narcotic control of the New York State Department of Health recently launched a survey to ascertain which private hospitals and sanatoriums are able to accept cases of narcotic drug addiction for treatment under the direction of a physician. On January 11 it was disclosed that the following places were available in the upper part of the state:

In the Buffalo area, the Edward J. Meyer Memorial Hospital, 462 Grider Street, Buffalo, under the direction of Dr. William T. Clark, will take such cases, at \$3.50 a day, with a minimum stay of twenty-one days required.

The Brigham Hall Hospital, Canandaigua, will take patients at rates from \$60 per week up, with a minimum stay of six weeks required.

In the Syracuse area the Twin Elms, 658 West Onondaga Street, Syracuse, under the direction of Dr. Eugene N. Boudreau, will take patients at a minimum of \$75 per week.

In Oneida the Oneida City Hospital and the Main Street Hospital will take a limited number of selected cases at rates from \$6 to \$7.75 a day for private rooms.

The Waterloo Memorial Hospital, Waterloo, will take 1 patient at a time, to be treated by a physician attached to this hospital, at rates from \$30 to \$35 per week.

In the Albany area Albany Hospital, Albany, under the direction of Dr. Severo E. Barrera, will accept cases at \$7 a day.

The Willows Nursing Home, Cedar Hills, under the direction of Dr. William B. Cornell, will take patients at \$35 and up per week.

Marshall Sanitarium, Linden Avenue, Troy, will take several such cases; rates are obtainable on request.

A list of places where treatment of addiction may be obtained in the New York City area had not as yet been compiled.

New York City

Division of Physical Medicine Created.—New York University has established a division of physical medicine, financed under a \$250,000 grant from the Baruch Committee on Physical Medicine, to specialize in research in physical and vocational therapy and in the preparation of technical personnel to rehabilitate both wounded war veterans and civilian disabled. The division will work in cooperation with the Bellevue Hospital and the Institute for the Crippled and Disabled and will be in charge of Dr. George G. Deaver, director of the university's program for training technicians in physical therapy and medical director of the Institute for the Crippled and Disabled. Dr. Deaver will have the title of clinical professor in charge of the new division at the university and physician in charge of physical medicine at Bellevue.

Health and Welfare Retirement Association.—The National Health and Welfare Retirement Association, Inc., a nonprofit organization, has recently been established with headquarters at 441 Lexington Avenue to assist certain

employees not eligible for benefits of old age security to participate with their employers in insurance coverage. It was stated that some 500,000 workers in private social, health and welfare agencies throughout the country will benefit. The new association was recently authorized by the New York State superintendent of insurance. Under the plan employees of the participating organizations normally may retire at the age of 65, with the option of retiring after reaching the age of 55. They will also be eligible to receive annuities for past and future services based on individual salaries.

Heart Association Separates from Tuberculosis Group.—The New York Heart Association, which has been a part of the New York Tuberculosis and Health Association, Inc., since 1926, is to set up as a separate organization on April 1, according to the *New York Times*. The expansion of the heart association program in the last few years was the reason given for the inadvisability of the organizations to continue their associated activities. The heart association will have offices at the New York Academy of Medicine, 2 East 103d Street. In the near future it will start a campaign to raise \$150,000 to finance itself during the next two years. The offices of the finance committee are at 331 Madison Avenue. Officers and directors of the heart association will continue under the newly formed corporation. Dr. Edwin P. Maynard Jr., Brooklyn, is president of the association, and Dr. Harold E. B. Pardee chairman of the finance committee.

NORTH CAROLINA

Appointments in State Department of Health.—Dr. Charles B. Davis Jr., Wilmington, has resigned as medical examiner of the North Carolina Shipbuilding Company to become director of the division of industrial hygiene of the state board of health, effective January 1. Dr. Davis succeeded Dr. Thomas F. Vestal, Raleigh, who has been named head of the division of tuberculosis control of the state board of health.

Academy Celebrates Seventy-Fifth Anniversary.—On February 2 the Raleigh Academy of Medicine, the oldest local medical organization in North Carolina which has preserved a continuous existence, celebrated its seventy-fifth anniversary at a dinner in the Hotel Sir Walter. Dr. Hubert A. Royster, Raleigh, served as toastmaster at the dinner and Major Gen. George F. Lull, deputy surgeon general, U. S. Army, gave the principal address, on "Some Wartime Problems of the Medical Department and Some of Its Accomplishments." Other speakers included an address by Dr. Vonnice M. Hicks, Raleigh, the president of the academy, Mayor Graham H. Andrews and Dr. Paul F. Whitaker, Kinston, president of the state medical society. Dr. Charles P. Eldridge, Raleigh, gave a review of the academy's history during the past twenty-five years. Greetings were read from Governor R. Gregg Cherry.

OHIO

Coroners' Association Formed.—The Ohio State Coroners' Association was recently organized, with E. R. Sturgis, East Liverpool, president; Dr. Robert T. Rowe, Medina, vice president and Dr. Demetrio M. Ceramella, New Philadelphia, secretary-treasurer. According to the *Ohio State Medical Journal* the coroners are the last group of elective county officials to form a state association.

OKLAHOMA

Hospital News.—Ground was broken recently for the construction of the new Norman Hospital on the site at Johnson Street and Ponca Avenue, Norman. Dr. John W. Shackelford, director of the local health service bureau, state health department, gave the principal address at the ceremonies.

Student News.—The students at the University of Oklahoma School of Medicine, Oklahoma City, under the sponsorship of the recently organized student council, on Dec. 9, 1944 published the first issue of the *Student Newspaper*, of which Mark R. Johnson, a member of the junior class, is editor. Plans are under way by the students in the medical school to publish the first yearbook in the form of a medical school annual to be devoted entirely to the medical school. J. Raymond Hinshaw, president of the junior class, is serving as editor of the book, which will consist of approximately seventy-five pages and will contain pictures of the faculty, students, buildings, student activities, a complete alumni directory and other items of interest. The publication of this annual is also sponsored by the student council.

OREGON

Telephone Employees Seek to Establish Own Fees.—

Oregon telephone employees through the medium of their recently incorporated Telephone Employees Hospital Association recently went over the heads of regular medical organizations, including the Oregon State Medical Society and the Oregon Physicians Service, and registered a direct appeal to individual physicians throughout the state through the following communication:

To All Physicians and Surgeons in Oregon:

The telephone employees have organized a hospital association among the employees only. We have worked out a list of fees with a group of doctors herewith enclosed for your approval. For your convenience in replying we are also enclosing a self addressed stamped envelop.

Thanking you in advance,

Yours very truly,

TELEPHONE EMPLOYEES HOSPITAL ASSN., INC.
M. E. BLANKENSHIP, Chairman.

After meetings of representative groups indicated that the telephone employees plan was not practical and in need of development, the question of approval of the plan or the fee schedule was not voted on but was left open for further discussions. *Northwest Medicine* reports that this is a definite crisis in the affairs of Oregon's doctors and a bold attempt to foist cut rate medical care on them and their patients under the guise of a poorly conceived prepaid plan. It points out that the door has not been closed to a proper consideration of the health problem of the telephone employees if they have one, indicating that the physicians of the state are aware of the distinctions between prepaid and cut rate medical schemes.

PENNSYLVANIA

Personal.—Dr. James A. Collins Jr. was chosen president recently of the Danville Board of Health.—Dr. Henry I. Klopp, superintendent of the Allentown State Hospital, Allentown, from 1912 until his retirement in July 1942, observed his seventy-fifth birthday, January 1.

Philadelphia

University News.—Of the nineteen living members of the class of 1895 of Woman's Medical College of Pennsylvania, six were present to receive the fifty year medal awarded by the Alumnae Association to members of the class during the ninety-third annual commencement, January 10. Dean A. Clark, senior surgeon, U. S. Public Health Service Reserve, delivered the commencement address, on "Trends in Medical Practice."

Federal Funds for Child Care.—Philadelphia received \$152,862 in federal funds January 19 to expand its child care services and check a downward trend in employment of women. The allocation will assist the board of education in expanding its facilities to accommodate 1,400 children, 800 preschool children between the ages of 2 and 6 and 600 school age children who are supervised before and after school. Most of the money will be used to help continue in operation nineteen war nurseries and child centers caring for 677 preschool and 567 school age children through June 30, to assist the board to establish another combined nursery center for 156 additional children.

Cancer Seminars.—A series of five seminars on cancer opened February 9 under the auspices of the committee on cancer control of the Philadelphia County Medical Society. The first was given on cancer of the head, neck and lung with Drs. George C. Yeager, George M. Dorrance, Wilbur Emory Burnett, Louis H. Clerf and John V. Blady. The second was held February 16 on cancer of the skin with Drs. Carroll S. Wright, Bernard P. Widmann, William E. Ehrlich, Henry A. Miller and Herman Beerman. Subsequent seminars will be devoted to cancer of the urinary tract February 23, cancer of the breast and uterus March 2 and cancer of the gastrointestinal tract March 9.

WEST VIRGINIA

Transfer of Center for Venereal Diseases to State.—

The Public Health Council of West Virginia has voted to accept the offer of the U. S. government to transfer to the state of West Virginia the Kanawha Valley Medical Center (rapid treatment center for venereal diseases), South Charleston. The transfer was unanimously approved by the council of the West Virginia State Medical Association. At a meeting to discuss the details of the transaction on January 18 it was brought out that the institution is now being operated at government expense under the supervision of the state health department; that the personnel consists of about 50, that the bed capacity is about 100, that an average of 245

cases are being treated each month and that the center is being operated by the government solely for the control and treatment of venereal diseases in a communicable stage. It was explained that, under state control, operation could be extended by the state health department so that patients could be given treatment until cures are effected, thus lessening the possibility that such patients would become state wards for the remainder of their lives. The medical center is one of fifty-five such institutions in the United States. It is said that more than a million dollars has been invested in the project. Most of the buildings were formerly used by the National Youth Administration. With the exception of possibly one clerk, all the expenses of the operation of the center for at least the next two years will have to be borne by the government, as no provision is made in the current budget bill for such expenses during the biennium beginning July 1, 1945.

GENERAL

Southern Medical Association Creates Section on Industrial Health.—

Announcement is made of the recent establishment of a section on industrial health within the Southern Medical Association. The officers include Drs. Charles W. Roberts, Atlanta, Ga., chairman, Oliver B. Zeinert, St. Louis, vice chairman and John J. Brandabur, Huntington, W. Va., secretary.

Special Society Elections.—Earl R. Serles, M.S., dean, University of Illinois College of Pharmacy, Chicago, was chosen president-elect of the American Pharmaceutical Association in a recent mail ballot. Other officers include A. Lee Adams, Glencoe, Ill., and Harold V. Darnell, Indianapolis, vice presidents. These officers will assume their positions at the next convention of the association. Robert P. Fischelis, Phar.D., Washington, D. C., is secretary of the American Pharmaceutical Association. Dr. Fischelis has resigned as director of the chemicals, drugs and health supplies division in the Office of Civilian Requirements, War Production Board, to become secretary and general manager of the association at its headquarters building in Washington (THE JOURNAL, Dec. 23, 1944, p. 1096).—Dr. Antonio A. Burke, Norfolk, Va., was chosen president of the Seaboard Medical Association of Virginia and North Carolina at its annual meeting in Wilson, N. C., December 5-7. Other officers include Drs. Ralph L. Fike, Wilson; Randolph B. Grinnan Jr., Norfolk; John E. G. McLain, Wilson, and Clayton W. Eley, Norfolk, vice presidents, and Dr. Clarence P. Jones, Newport News, Va., secretary-treasurer. The fiftieth anniversary meeting will be held at Virginia Beach, Va., in the autumn.

Decrease in Marriages Predicted.—The increase of the marriage rate by the entrance of the United States into the war has about run its course, and the country is entering a period when marriages will fall even below the peacetime average, according to statisticians of the Metropolitan Life Insurance Company. A release discussing the situation pointed out that 1944 was the second successive year in which the marriage rate for the country as a whole declined from the peak established in 1942. While overall figures show a decline in marriages, the statisticians find many variations in pattern in the records of individual cities of 100,000 population or more. In general, cities of New England and of the Middle Atlantic and East North Central states have experienced a decline in marriages ever since 1942. In urban centers of the West North Central states as a whole the decline began only in 1943, while among Southern urban centers the decline did not set in until 1944. An actual increase in marriages is reported in 1944 in the larger cities of the Mountain and Pacific Coast states, although the gain over the preceding year was small. Using 1941, the last prewar year, as base the statisticians find that the decrease in marriages graded from east to west, with the sharpest declines among New England cities and lesser reductions westward through the Middle Atlantic, East North Central and West North Central states. New York and Chicago fell behind year by year, while in Philadelphia and Detroit the decline began after 1942. Decreases of more than 40 per cent over the three year period were reported among others from Cincinnati, Toledo and Youngstown, Ohio. While the South reported its first decline in 1944, only four of its cities had fewer marriages than in 1941. Norfolk, Va., site of an important naval base, more than doubled its 1941 marriages in 1944, and 75 per cent increases were recorded in Jacksonville, Miami and Tampa, Fla. Marriages in the large cities of the Mountain and Pacific Coast states as a whole showed a 70 per cent increase in 1944 over 1941. In California, San Diego had about three and one-half times the number of its 1941 marriages. This increase is

attributed to a large naval base and the growth of neighboring aviation industries. Marriages in San Francisco, Sacramento and Oakland more than doubled, while farther north along the coast, Spokane, Wash., almost doubled its rate. However, the statisticians anticipate a reversal in the trend for Mountain and Pacific Coast states during 1945. Two main factors emerge as causes of the recent conflicting local changes in marriages: the migration of population brought about by war industries and the induction of young men into the armed services. Despite the recent great fluctuations, the insurance company's statisticians believe that later on, when the marriage rates for the periods immediately preceding and immediately following the war, together with the war period itself, can be observed, the general average of the marriage rate over the period as a whole will not be very far different from the usual peacetime figure.

Vitamin Research Institute Organized.—The Vitamin Research Institute was formed at a meeting in the Waldorf-Astoria, New York, January 29 and represents the first effort of the vitamin industry to collect and correlate on its own behalf, for guidance of its members, the medical profession, health authorities and educational institutions, data that formerly had been gathered by individual researchers and subjected to a variety of interpretations within and outside the trade, according to the *New York Herald Tribune*. The meeting was attended by representatives of forty companies in the field. The new institute will be financed through annual dues based on the annual volume of sales of each member. In addition, some studies will be initiated through special grants by manufacturers and distributors. In a statement to the press Dr. Theodore G. Klumpp, New York, president of Winthrop Chemical Company, a member of the organizing group, said that "the activities would take three general forms: laboratory studies of vitamin deficiencies; clinical deficiency inquiries, including greater study of the so-called borderline deficiency cases, and epidemiological investigations into such subjects as the incidence of deficiencies among various income, geographical and occupational groups." The objectives of the newly organized institute are:

To promote and encourage the study of problems in nutrition, particularly as they relate to vitamins, toward the end that the health and welfare of mankind may be improved through better nutrition.

To initiate, promote, assist, develop, maintain, conduct and carry on, directly or indirectly, studies, investigations and research in any way relating to medicine and health and without limiting in any way the generality of this purpose, in particular to initiate, promote, assist, develop, maintain, conduct and carry on, directly or indirectly, studies, investigations and research in any way relating to vitamins and any subject directly or indirectly related thereto.

To make voluntary contributions or grants of money from the funds of the institute at any time and from time to time to individuals, partnerships, corporations, organizations or institutions to conduct, carry on or continue any such studies, investigations and research.

To provide, establish and maintain scholarships, fellowships and other aids or facilities for such studies, investigations and research.

To obtain, collect, disseminate and distribute to members of the vitamin industry, the professions, public health authorities and educational institutions information as to the quality, purposes, uses and effects of vitamins and their relation to nutrition and health.

To study, adopt and recommend proper standards and terminology for use in connection with the manufacture and sale of vitamin products.

To study, adopt and recommend standards of publicity practices for use in connection with the sale of vitamin products and to discourage improper practices in connection therewith.

Membership has been divided into four classifications:
Professional: Firms that manufacture packaged vitamin products which are promoted primarily to the profession, including physicians, pharmacists, dentists and veterinarians.

Consumer: Firms that manufacture packaged vitamin products which are merchandised primarily by means of direct consumer advertising, such as radio, newspaper and direct mail.

Basic Producers: Firms whose major interest in the vitamin industry is the supplying of vitamins in bulk to manufacturers and distributors.

Honorary: Persons who, because of their scientific achievement or position, are invited to membership in the institute by the membership committee.

A board of governors was named consisting of nineteen members to serve as the controlling body of the institute. The

direct business and executive management will be vested in an executive committee appointed by the board of governors, and the detail operation shall be conducted by an executive secretary.

FOREIGN

Personal.—Brigadier George MacDonald, emeritus professor of physiology of the University of Liverpool, has been promoted to be director of the Ross Institute of Tropical Hygiene of the London School of Hygiene and Tropical Medicine; he has been assistant director of the institute since 1939.

CORRECTION

Para-Aminohippuric Acid.—In the article by Beyer et al. (*THE JOURNAL*, Dec. 16, 1944, p. 1007) the second last line of the second column should read (47.7 to 46.9 mg. per hundred cubic centimeters). The word "hundred" was inadvertently omitted as published.

Government Services

Health Services for All Mothers and Children After the War

A nationwide survey of personnel and facilities needed to assure comprehensive health services for all mothers and children after the war, which will be undertaken by the American Academy of Pediatrics with the help of the Children's Bureau, United States Department of Labor, and the Public Health Service, Federal Security Agency, received the endorsement of seventy leading physicians and other professional workers meeting in Washington as an advisory committee to the Children's Bureau, the Department of Labor reported recently. This action of its advisory committee and others bearing on the administration of the Children's Bureau maternal and child health program were made known by Dr. Martha M. Eliot, associate chief of the bureau. Chairmen of the committee are Dr. Nicholson J. Eastman, professor of obstetrics at the Johns Hopkins University School of Medicine, Baltimore, and Dr. Henry F. Helmholz, chief of the pediatric department of the Mayo Clinic, Rochester, Minn. Supporting the recently declared objective of the Academy of Pediatrics to make available to all mothers and children in the United States all essential preventive, diagnostic and curative medical services of high quality, which, used in cooperation with the other services for children, will make this country an ideal place for children to grow into responsible citizens, the Children's Bureau advisory committee urged full cooperation in the projected survey. Dr. Eliot reported that the advisory committee also approved the position recently taken by the Academy of Pediatrics in regard to the financing of any extension of medical services for children that "cannot be reduced to any one simple formula." It may be provided for by direct payments to the physician by the family, by voluntary or compulsory insurance plans or by tax supported local, state or federal programs. Recognizing that any comprehensive health program will be possible only if facilities and personnel are available, the advisory committee laid special stress on building up medical and nursing staffs in hospitals and on training more obstetricians, pediatricians, nurses and social workers in the care of mothers and children. Grants for research were urged. One national goal, the committee held, should be "the delivery of all women in good hospitals under the care of competent physicians." To this end the committee directed attention to the need for building more maternity units as parts of general hospitals. "It would be highly desirable that the general hospitals be health centers designed to supply all types of medical service to a given area," the committee said. More beds for babies and older children in general hospitals and better facilities for the care of premature and newborn infants are needed, and "the establishment of children's hospitals in association with general hospitals or medical school units is to be encouraged," the committee said. Tackling the problem of the health of school children, pointed to by Dr. Eliot as "one of our most serious neglects, revealed by draft rejections," the committee called for the creation in the Children's Bureau of a special unit on school health to work in cooperation with the United States Office of Education, Federal Security Agency. It also urged local, state and federal authorities to help local departments of health and education to establish good working relations in providing preventive and curative health programs for school children.

The Treatment of Wound Shock

In 1940 the Medical Research Council issued a memorandum for the guidance of medical officers on the treatment of wound shock. The experience of four years of war and research has made necessary a new edition, which differs extensively from the first edition. The original recommendations have in the main stood the test of time well, but points of emphasis have changed and new modifications of treatment have become important. In the war of 1914-1918 emphasis was laid on the circulatory effects of injury, especially those resulting from decreased blood volume. It is now appreciated that the remote effects of injury also comprise such diverse effects as renal failure in crushing injuries, systemic effects in burns, fat embolism and severe complicating bacterial infections. Two or more of these conditions may be present, producing a complicated clinical picture. Operations and anesthetics by themselves may reduce blood pressure, it is pointed out. In battle, explosive gases or exhaust fumes in confined spaces may cause poisoning, for example by carbon monoxide. Following severe injuries of different organs and tissues, resulting circulatory depression may have various underlying mechanisms: head injuries, chest injuries, abdominal injuries and limb injuries all have special features. Shock is therefore not a single entity, the memorandum emphasizes. It is generally agreed that a major feature of shock in these cases is oligemia. In the last war oligemia was regarded as something rather mysterious, but it is now generally believed to result from loss of blood and plasma externally or into the traumatized area.

When oligemic shock is severe there is no known measure other than transfusion that will save life. But when oligemia is due to toxic gases such as phosgene, mustard gas and lewisite, which induce lung irritation or predispose to pulmonary edema through absorption from the skin, transfused fluid leaves the circulation through the damaged capillaries and there is experimental evidence that transfusion is not only useless but harmful. When as a result of injury the systolic blood pressure is below 90 mm. of mercury and the pulse is rapid, transfusion should not be delayed, it is declared. Transfusion should not be withheld under these circumstances no matter how near death the patient appears to be. The apparently moribund and pulseless patient may sometimes be resuscitated by massive transfusion.

Cancer Research

At the annual meeting of the British Empire Cancer Campaign F. L. Hopwood, vice dean and professor of physics, St. Bartholomew's Hospital, said that with sober pride and thankfulness they could say that three aims of the campaign—to investigate the causation, cure and prevention of cancer—had been considerably advanced in the past twenty-one years. Regarding the cure of cancer, he stated, they could view the future with ever increasing confidence. Their satisfaction that carcinoma of the prostate could in many instances be controlled by the synthetic estrogen diethylstilbestrol was enhanced by the knowledge that this compound was first synthesized by Professor Dodds, working in association with Sir Robert Robinson and their respective teams. The alluring prospect was opening up of combining radiation therapy and chemotherapy in a new attack on cancer, Professor Hopwood said. The new forms of radiation and the supply of adequate quantities of artificially prepared radioactive substances required such powerful apparatus that they could probably be installed only

in special institutes staffed by teams of specialists, including experts in all the basic medical sciences, he thought. The cost would be high, but the outlook was sufficiently promising to justify it many times over. Obviously the new radiations and radioactive substances must also have application in agriculture and industry. The scientific committees of the campaign were giving careful attention to the question of how best to avail themselves of these new agents and to collaborate with other interested national bodies, Professor Hopwood added.

ICELAND

(From Our Own Correspondent)

Jan. 27, 1945.

The Military Occupation

In May 1940 British forces occupied Iceland, and a little more than a year later, or July 7, 1941, American forces moved into Iceland, before the United States had entered the war.

The occupying forces have been received with general understanding by the population. Iceland has no army, and for centuries the Icelanders have been among the most peaceful of nations, their only enemy being the elements, which in the form of storms, earthquakes and volcanic eruptions have taken as many lives as other nations lose in wars. Criminality has been low, and a murder has not been committed here since 1929. Although the population is small (only 130,000) this is an unusually low rate of homicide.

When the Americans came some soldiers used their guns as the final argument in disputes, which horrified the Icelanders. After a few killings of Icelanders prevention taken by the authorities on both sides seems to have been effective, for such cases do not occur any more. Misunderstandings are bound to take place under such circumstances, and these unfortunate incidents have been handled with tact and understanding by the respective authorities.

Venereal Diseases

As Iceland has had a low rate of venereal diseases, a considerable increase was expected owing to the great inflow of soldiers to the country. But although the communication between soldiers and the female population has been about the same here as anywhere else, it is a fact which gives high credit to the medical service of the American military forces that venereal morbidity has increased but little since the occupation. Before the war there were only about 14 fresh cases of syphilis a year in the whole country. In 1943 there were 82. But gonorrhea had dropped from 492 in 1939 to 233 in 1943, which is evidently due to the introduction of the sulfonamides. The chief source of venereal infection has not been the military forces but the merchant marine, composed of various nationalities. Most of the syphilitic infections have been traced to British ports.

Absence of Quackery

A number of Icelandic patients with difficult diseases which required special treatment have been flown over to America by permission of the American military authorities. The Icelanders have great respect for American medicine, and American doctors have seen that medical education at the University of Iceland is on a sound basis. General education ranks high in Iceland, and consequently quackery and charlatanism find a meager soil here. Osteopaths and chiropractors do not exist and could not find a means of subsistence. To practice medicine one has to have the university examination and a year's internship in a recognized hospital, all of which takes seven or eight years of medical study. If anybody else wants to practice medicine, no matter under how high sounding a title, he is not allowed to advertise or introduce himself under any title but one, which must be on his sign and prescriptions: *skottulækknir*, which means quack doctor. This legislation solves the whole

problem in an easy manner. In direct consequence of this course is the law which prohibits advertising of drugs of all kinds in all papers except those of the medical profession.

A systematic search for tuberculosis has just been started in Reykjavik. Every one of Reykjavik's 42,000 inhabitants will be examined by x-ray miniature film equipment and suspects picked out for further examination. Dr. S. Sigurdsson has been leading the fight against tuberculosis with great success, the mortality being now only 83 against 216 per hundred thousand fifteen years ago. This is the first examination of this kind in a European capital, and the start is promising, as everybody seems willing to cooperate.

The American influence is making itself more and more felt also in the medical field. Young doctors, who used to go to Denmark and Germany for advanced studies, are now practically all going to the United States, where their admiration and surprise are balanced between the impressive efficiency and high standard of American medicine and the vast amount of quackery thriving in its shadow.

Medical Cooperation

Cooperation between American and Icelandic doctors has been excellent, and the Americans have been helped in various emergencies, as when air transport has been needed for a patient in some distant part of the country or when some essential drug has run out of stock in the Icelandic pharmacies.

Major Edward Haboush, orthopedic surgeon from New York, became popular among the Icelanders for operating with success on one of the leading Icelandic doctors, who was supposed to have a prolapsed intervertebral disk but was found to have a bony outgrowth compressing the posterior nerve roots. Last winter the Medical Society of Reykjavik invited their American colleagues to a joint meeting, which was successful in promoting good will and mutual understanding.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, Dec. 15, 1944.

Experimental Epilepsy in Frogs

Dr. Miguel Ozorio de Almeida of the Division of Physiology of the Oswaldo Cruz Institute has published a new contribution in his series of experimental studies of the physiopathology of the nervous system. Dr. de Almeida reports results obtained in the production of epileptiform attacks induced in the Brazilian frog *Leptodactylus ocellatus* by sudden cooling of the spinal cord after section. This phenomenon, which the author calls cryoepilepsy, is the first instance so far reported in medical literature of experimental epilepsy of purely spinal origin; all attempts to obtain epileptiform attacks through electrical or chemical incitement have been negative. The attack may be influenced by various factors, among which the chief ones are the length of the spinal centers preserved in the preparation, the influence of the upper nervous centers, the inhibiting or facilitating action of external incitations simultaneously applied during the cooling period, and the effects of the labyrinthine reflexes. One of the most interesting effects is the state of hydration of the tissues. The loss of water by evaporation causes notable alterations in the characteristics of the attack, some of which result from the changes in the functions of the muscles and the peripheral organs and some from changes in the nervous centers. The report also contains a summary of Dr. de Almeida's researches on the value of the "latent period" of the attack, i. e. the interval between the beginning of the cooling and the first clear symptoms of the convulsive crisis. This latent period is variable according to the conditions under which the experiment is performed and the state of the frog preparation.

Characteristics of the cryoepilepsy attacks vary according to the species under experimentation and the habitual living conditions of the animals. Animals of the same species, but living in different climates, display conspicuous differences in the upper limit of temperature which induces the attack. This was strikingly demonstrated by the experiments performed with *Leptodactylus ocellatus* in several South American cities with different mean annual temperature (Buenos Aires and Montevideo 61 F., Rio de Janeiro 72 F., Recife 79 F.), the upper limit of critical temperature varying from 41 F. in the first two cities to 54 F. in the last. In addition to the variation in the upper limit of temperature, the cryoepileptic attack shows differences in form in animals living in places of identical climates, as is the case with *L. ocellatus* of Montevideo and Buenos Aires, such differences being probably due to variation in the composition of the water in which the animals live and also perhaps to differences of food. North American and European frogs display the attack only if the spinal cord is cooled to temperatures far lower than those at which a positive result is obtained operating on animals from hot climates. It would seem, however, that these characteristics may show a slow and progressive change as the result of adaptation to new living conditions. Specimens of *Rana catesbeiana* brought from the United States and acclimatized in a hot climate such as that of Cuba show the attacks at a temperature noticeably higher than those observed in North America in frogs of the same species.

Brief Items

The ambassador from Uruguay unveiled recently at the Medical School of the University of Rio de Janeiro a plaque offered by the Medical School of the University of Montevideo in honor of the late Professor Dr. Helion Povoá, who pioneered scientific exchanges between Uruguay and Brazil.

Dr. Fraga de Azevedo and Dr. Salazar Leite, respectively director and member of the Institute of Tropical Medicine of Lisbon, Portugal, spent several days in Rio de Janeiro studying the organization and work of the Oswaldo Cruz Institute. They were received at the National Academy of Medicine and at the Ministry of Health.

The Brazilian Society of Clinical Radiology has elected to its governing board for the year 1945 Drs. Roberto Duque Estrada, Gil Ribeiro, Jaime Rosado, J. Pires Magalhães and Alcides Lopes.

Marriages

ROBERT BURNS McEWLEN, Wakefield, Va., to Miss Maisie Askew of Suffolk, Va., in Washington, D. C., November 3.

WILLIS EDMUND MANGES, Philadelphia, to Miss Virginia Claire Bernhard of Bryn Mawr, Pa., November 12.

GEORGE EDWARD PRINCE to Miss Millie Elizabeth Mann, both of Dunn, N. C., in New York, November 26.

WILLIAM ALDEN HOGGARD JR., Hertford, N. C., to Miss Dora Glenn Granger of Lake City, Fla., November 8.

JAMES W. WOODS JR., Lewisburg, Tenn., to Miss Marion Briner of Bethlehem, Pa., November 26.

STUART WYNN GIBBS, Erwin, N. C., to Miss Sara Jean Bowen of Winston-Salem, December 16.

DOUGLAS WALDEMAR LUND to Miss Hazel Jean Tavernetti, both of Berkeley, Calif., October 19.

JAMES A. FORT JR., North, S. C., to Miss Mary Lavinia Owen in Columbia, December 10.

ARAM GLORIG JR., Atlanta, Ga., to Miss Margaret Denham of London, England, recently.

MAURICE S. SANDERSON to Miss Dorothy Young, both of Waco, Texas, November 18.

GEORGE JACK PRUITT to Miss Betty Landrum, both of Houston, Texas, December 21.

Deaths

William Henry Howell, Baltimore, noted physiologist, died February 6 of heart disease, aged 84.

Dr. Howell was born in Baltimore, Feb. 20, 1860. He received the A.B. degree at Johns Hopkins University in 1881 and Ph.D. in 1884. In 1890 the University of Michigan Medical School conferred on him an honorary M.D. degree and he was licensed to practice medicine in Maryland. In subsequent years he received other honorary degrees from Trinity College, Michigan, Washington University, the University of Edinburgh and Yale University. Dr. Howell had been associate professor of physiology at Johns Hopkins University Medical School for a year in 1888. He was professor of physiology and histology at the University of Michigan Medical School from 1889 to 1892, when he went to Harvard Medical School for a year as associate professor of physiology. He was professor of physiology at Johns Hopkins from 1893 to 1931, dean of the faculty of medicine from 1899 to 1911 and assistant director of the School of Hygiene and Public Health from 1917 to 1926, when he was named director. He had been emeritus since 1931.

Dr. Howell held membership in numerous scientific groups including the National Academy of Sciences, the American Philosophical Society, the Society for Experimental Biology and Medicine and the American Physiological Society. In 1929 he was president of the thirteenth International Physiological Congress in Boston, in 1932-1933 chairman of the medical section of the National Research Council, and one of the first members to be named to the National Advisory Health Council. He was an honorary member of the English Physiological Society, associate member of the Medical and Chirurgical Faculty of Maryland and a member of the American Medical Association. Dr. Howell had contributed extensively to the literature on his specialty. He was editor of *An American Text-Book of Physiology*, 1896, author of a textbook of Physiology in 1905 and at one time associate editor of the *American Journal of Physiology*. In 1920 he with Dr. W. H. Welch founded the *American Journal of Hygiene*. In 1937 the Finney-Howell Research Foundation was created by the will of the late George Walker to honor Dr. Howell and the late Dr. John M. T. Finney. There is also a student award at the Johns Hopkins medical school which bears his name. In 1938 Dr. Howell's contribution to the fiftieth anniversary celebration of the American Physiological Society was the preparation of the first twenty-five years' history of the society. In the same year he was named a member of the newly created committee on industrial health of the Medical and Chirurgical Faculty of Maryland. In 1933 he was a member of the advisory committee of sanitation of the Baltimore Health Department.

He won an international reputation for his research on the origin of red blood corpuscles, degeneration and regeneration of nerve fibers, causation of the rhythmic beat of the heart, mechanism of sleep, relation of the inorganic salt of the blood to the beat of the heart, proteins of blood serum, coagulation of the blood and similar studies. Dr. Howell participated notably in the discovery of heparin; he also did original research on the mechanism of production of blood platelets.

Charles MacLachlan ☉ New Rockford, N. D.; M.B., University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1889 and M.D., Victoria University Medical Department, Coburg, Ont., Canada, 1889; member of the House of Delegates of the American Medical Association in 1916, 1918, 1929 and 1930; honorary member of the North Dakota State Medical Association; for two terms member of the first North Dakota Board of Medical Examiners; member of the state legislature, 1894-1895; member of the board of trustees of the State Hospital for Insane; vice president of the state board of health in 1894; surgeon general, North Dakota National Guard, from 1895 to 1911 with rank of colonel; president of the North Dakota State Medical Association in 1909; president and coorganizer of the Tri-County Medical Society; president of the State Game and Fish Board from 1916 to 1920; superintendent of the North Dakota State Tuberculosis Sanatorium at San Haven from 1929 to 1937; served as county coroner of Eddy County; honorary president of the International Peace Garden, Inc.; died October 7, aged 83, of bronchopneumonia and senility.

John Richard Kevin ☉ Brooklyn; Bellevue Hospital Medical College, New York, 1888; member of the House of Delegates of the American Medical Association from 1920 to 1925, from 1927 to 1931 and 1935-1936; fellow of the American College of Surgeons; past president of the Kings County Medical Society and the Medical Society of the State of New York; since 1913 member of the New York State Board of Social Welfare; served as member and vice president of the

state board of charities; formerly member of the board of education and board of aldermen; surgeon of the twenty-third regiment, New York National Guard, from 1909 to 1916; at one time on the staff of the Downtown Hospital; for many years on the staff of St. Mary's Hospital, where he died January 8, aged 81, of lobar pneumonia and arteriosclerotic heart disease.

Antoine Joseph Schneider ☉ Washington, D. C.; Johns Hopkins University School of Medicine, Baltimore, 1927; professor of neurology at the Georgetown University School of Medicine; specialist certified by the American Board of Psychiatry and Neurology, Inc.; interned and formerly resident physician at the Boston City Hospital; interned at St. Elizabeths Hospital; original member of the District of Columbia Mental Health Commission; appointed a lieutenant commander in the medical corps, U. S. Naval Reserve, on Oct. 29, 1941; reported for active duty on Nov. 12, 1941; released from active duty on Dec. 5, 1941; honorably discharged on Jan. 3, 1942 for physical disability; consultant in neuropsychiatry at the Mount Alto Hospital; died December 27, aged 41, of cerebral hemorrhage.

Ernest Lawrence Meland ☉ Minneapolis; University of Minnesota Medical School, Minneapolis, 1926; served as clinical assistant professor of urology at his alma mater; member of the American Urological Association and the North Central Branch of the American Urological Association; since 1939 member of the board of directors of the Hennepin County Medical Society; specialist certified by the American Board of Urology, Inc.; secretary of the Alumni Association of the Mayo Foundation; formerly fellow in urology at the Mayo Foundation, Rochester, Minn., where he served as first assistant in operative surgery from Jan. 1 to Oct. 1, 1932; interned at the Minneapolis General Hospital; on the staff of the Abbott Hospital; died December 3, aged 43, of hypernephroma.

Leon Thomas Ashcraft, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1890; professor and head of the department of urology at his alma mater; fellow of the American College of Surgeons; urologist on the staffs of the West Jersey Homeopathic Hospital, Camden, N. J., Women's Homeopathic and Broad Street hospitals; consulting urologist, Carlisle Hospital, Carlisle, Homeopathic Hospital, West Chester, Homeopathic Hospital, Pottstown, Wyoming Valley Homeopathic Hospital, Wilkes-Barre, and the William McKinley Memorial Hospital, Trenton, N. J.; in charge of the department of urology at the Hahnemann Hospital, where he died January 19, aged 78, of coronary thrombosis.

Norman Harris Williams ☉ Los Angeles; Johns Hopkins University School of Medicine, Baltimore, 1913; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; president-elect and formerly secretary and vice chairman of the Pacific Coast Society of Obstetrics and Gynecology; fellow of the American College of Surgeons; interned at the Cornell Division, Bellevue Hospital, New York; formerly assistant resident at the Memorial Hospital in New York and assistant resident and resident at the Manhattan Maternity Hospital and Dispensary in New York; on the attending staff of the Hospital of the Good Samaritan; died December 18, aged 57, of coronary thrombosis.

Thompson Flournoy Wickliffe ☉ Jasper, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1903; member of the American Academy of Ophthalmology and Otolaryngology and the Southern Medical Association; specialist certified by the American Board of Otolaryngology; on the staffs of the Peoples and Walker hospitals; formerly acting assistant surgeon in the U. S. Public Health Service; at one time in charge of the United States Trachoma Hospital in London, Ky.; died in the Highland Avenue Baptist Hospital, Birmingham, November 26, aged 64, of subacute bacterial endocarditis.

Ralph Maurice DeGraff ☉ Buffalo; University of Buffalo School of Medicine, 1915; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc.; treasurer of the Medical Society of the County of Erie; assistant in radiology at his alma mater; on the staff of the Children's Hospital as attending radiologist; consulting roentgenologist at the J. N. Adam Memorial Hospital, Perrysburg, and the U. S. Marine Hospital; consultant in x-ray, medical advisory board number 49, Selective Service for New York State; died December 13, aged 52.

John Henry Gemmell, Philadelphia; University of Minnesota Medical School, Minneapolis, 1928; member of the Radiological Society of North America, Inc., and the American College of Radiology; specialist certified by the American Board of Radiology, Inc.; interned at the Bellevue Hospital in New York; instructor in radiology at the Temple University School

of Medicine; formerly radiologist at the Beaver Valley General Hospital, New Brighton, Pa., and the Rochester General Hospital, Rochester, Pa.; died December 1, aged 40, of coronary occlusion.

Horace Herbert William Ard, Dearborn, Mich.; Detroit College of Medicine and Surgery, 1916; interned at the Grace Hospital in Detroit; served during World War I; died December 12, aged 56, of coronary thrombosis.

Albert Josef Baer, Milwaukee; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1922; member of the American Medical Association; on the staffs of the Mount Sinai, Columbia, St. Michael, St. Mary's and St. Joseph's hospitals; medical director of the Lakeside Laboratories; died in the Lake County Sanatorium, Waukegan, Ill., December 10, aged 46, of tuberculosis.

Frederic Leslie Ball, Bremerton, Wash.; George Washington University School of Medicine, Washington, D. C., 1938; interned at the Swedish Hospital, Seattle; newly elected president of the Kitsap County Medical Society; on the staff of Franklin Delano Roosevelt Hospital; died December 17, aged 43, of coronary thrombosis.

Frank D. Baumann, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1910; served during World War I; died December 11, aged 55, of bronchiectasis.

John Belcher Beebe, Great Barrington, Mass.; Albany Medical College, Albany, N. Y., 1893; a director of the National Mahaiwe Bank, South Berkshire; retired medical examiner; served on the school committee; on the staff of the Fairview Hospital; died January 25, aged 75, of myasthenia gravis.

Claes Gustav Anton Biorkman, New York; College of Physicians and Surgeons, Los Angeles, 1918; served as consulting physician for the Swedish-American Line; interned at the Children's Hospital in Boston; director of physical therapy at the Gotham Hospital, where he died December 25, aged 64, of coronary thrombosis.

Edwin T. Black, Huntsville, Ill.; Rush Medical College, Chicago, 1881; died December 10, aged 86, of heart disease and arteriosclerosis.

Harold LaVerne Blosser, Portland, Ore.; Harvard Medical School, Boston, 1925; diplomate of the National Board of Medical Examiners; president of the state board of medical examiners; member of the council of the Multnomah County Medical Society; medical adviser to the Multnomah division of Oregon Physicians Service and chairman of its supervisory committee; died November 3, aged 46, of coronary thrombosis.

John Edward Bowman, Broken Bow, Neb.; Cotner University Medical Department, Lincoln, 1912; member of the American Medical Association; secretary of the Custer County Medical Society; on the staff of St. Francis Hospital, Grand Island; died in the Bishop Clarkson Memorial Hospital, Omaha, November 15, aged 66, of embolism.

John Harris Brown, Clifton, N. J.; University of Vermont College of Medicine, Burlington, 1914; member of the American Medical Association; died November 28, aged 58, of coronary occlusion.

Turner Harris Brown, Carlisle, Ky.; Ensworth Medical College, St. Joseph, Mo., 1912; member of the American Medical Association; died in the Harrison Memorial Hospital, Cynthiana, December 12, aged 64, of cerebral hemorrhage.

Robert Irving Bullard, Springfield, Ill.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; fellow of the American College of Surgeons; served during World War I; on the staffs of the Memorial Hospital and St. John's Hospital, where he died December 25, aged 67, of asthma.

Richard Carey, Macon, Ga.; Howard University College of Medicine, Washington, D. C., 1894; served as secretary of the medical section of the John A. Andrews Clinical Society; formerly on the staff of the Veterans Administration Facility, Tuskegee, Ala., and consultant to the John Albion Andrew Memorial Hospital, Tuskegee Institute; died in the Presby-

terian Hospital, New York, January 13, aged 73, of sepsis and osteomyelitis.

Belton Drafts Caughman, Columbia, S. C.; University of Maryland School of Medicine, Baltimore, 1911; member of the American Medical Association; served during World War I; died November 30, aged 59, of coronary thrombosis.

Deodatus Tancrede Chagnon, Lawrence, Mass.; M.B., 1903 and M.D., 1904, School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal; died in Chelsea October 2, aged 64, of coronary heart disease and general arteriosclerosis.

Earl Burrell Craig, Elkins Park, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1906; Jefferson Medical College of Philadelphia, 1908; professor and head of the department of gynecology at the Hahnemann Medical College and Hospital of Philadelphia; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; fellow of the American College of Surgeons and the International College of Surgeons; head of the department of gynecology, Hahnemann Hospital, Philadelphia, where he died December 17, aged 63, of carcinoma of the lung.

Thomas Joseph Dion, Quincy, Mass.; M.B., Laval University Faculty of Medicine, Quebec, 1890; M.D., School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1891; member of the American Medical Association; member of the board of health from 1900 to 1905 and of the school board from 1900 to 1903; city physician from 1916 to 1922; on the staff of the Quincy City Hospital; died in the Boston City Hospital November 27, aged 76, of cerebral hemorrhage and bleeding gastric ulcer.

Oscar Albert Dudley, Shrewsbury, Mass.; College of Physicians and Surgeons, Boston, 1907; Massachusetts public health officer for the Worcester district for many years; decorated with the Croix de Guerre by the French government for heroism during World War I; for many years held a commission in the Massachusetts National Guard, retiring as colonel in 1939; died October 28, aged 60, of bronchopneumonia.

John Philip Hawkinson, Crosby, Minn.; University of Minnesota Medical School, Minneapolis, 1926; member of the American Medical Association; served as president of the Upper Mississippi Medical Association; interned at the Minneapolis General Hospital; at one time mayor of Crosby; on the staff of the Miner's Hospital; died October 19, aged 48, of coronary thrombosis.

Arnold Peskind, Cleveland; University of Wooster Medical Department, Cleveland, 1887; Jefferson Medical College of Philadelphia, 1887; president of the East 55th Street Hospital; died October 30, aged 81, of pulmonary infarction.

Abram Edson Platter, Memphis, Mo.; University Medical College of Kansas City, 1896; member of the American Medical Association; past president of the Scotland County Medical Society; served as county health officer; died October 20, aged 78, of hypostatic pneumonia complicated by mitral insufficiency.

Ernest Hansen Smith, Los Angeles; Chicago Homeopathic Medical College, 1891; died November 10, aged 81.

KILLED IN ACTION

Gordon Allen Pracher, Tecumseh, Neb.; University of Nebraska College of Medicine, Omaha, 1932; member of the American Medical Association; served an internship at the Northern Pacific Beneficial Association Hospital in St. Paul; formerly resident physician at the Northern Pacific Hospital, Glendive, Mont., St. Luke's Hospital, St. Louis, Chicago Maternity Center, Chicago, St. Louis Maternity Hospital, St. Louis, and the Community Hospital, Battle Creek, Mich.; commissioned a first lieutenant in the medical corps, Army of the United States, on Oct. 16, 1942; later promoted to captain; killed in action in Italy, May 28, 1944, aged 36.

CAPT. GORDON ALLEN PRACHER,
M. C., A. U. S., 1907-1944

Correspondence

"MALE CLIMACTERIC"

To the Editor:—In THE JOURNAL, Oct. 21, 1944, page 472, is an article entitled "Male Climacteric" by Heller and Meyers. Under "Results of the Therapeutic Test in Patients with High Gonadotropins (Group B)" the authors state that "on resumption of the therapy with testosterone propionate relief of symptoms was again afforded and sexual potency returned. Thus the specificity of therapy was established." This statement is not entirely true. It is admitted that testosterone can produce such a result, but so can estradiol and diethylstilbestrol, for I have been able to study personally three men so treated. Consequently, testosterone propionate is not proved to be a specific for the male climacteric.

The authors list pruritus as a psychic symptom. The pruritus that one sometimes sees with the climacteric, male or female, is a definite deficiency disease syndrome and is far from psychic in the general sense of the word. Actually this syndrome is much commoner after the sixth decade and is generally known as essential senile pruritus. Some years ago Feldman, Pollock and I published a preliminary report of our findings (*Arch. Dermat. & Syph.* 46:112 [July] 1942) in which we found that estradiol or testosterone could abolish this syndrome in both men and women. Since then I have found that methyl testosterone, diethylstilbestrol and various other estrogens can also relieve essential senile pruritus.

The authors assume that there is a decrease in libido and potentia in cases of true male climacteric. Castration in the adult male does not necessarily lead to impotence. I know of a man aged 75 who had had a bilateral orchiectomy for carcinoma of the prostate. This man was receiving 2 mg. of diethylstilbestrol daily when he came in with a textbook picture of anterior gonorrheal urethritis. In one of the cases treated with estradiol, potentia not only remained unimpaired but when the flashes and nervousness were abolished libido actually increased.

Can we scientifically say that hot flushes in the female climacteric are physiologic and the same symptom in the male is pathologic? In other words, a male is not normal if his gonads begin to regress before he departs from this world. Surely we will all agree that the process of aging can become manifest to a clinical degree in various organs and systems at varying times. Just because the testis is one of the last to succumb does not mean that it has now become the site of a pathologic process while a similar state in the ovary is merely physiologic.

The last point I would raise is whether testicular failure per se is responsible for the male climacteric. I have seen 2 patients aged 23 and 25 respectively who had a complete aspermia. Testicular biopsy in each case revealed absence of spermatogenesis and yet neither had any symptoms of the climacteric. Libido and potentia were normal. Further, not every man undergoing bilateral orchiectomy develops a syndrome of the male climacteric. Sometimes these postpubertal castrates do not develop flushes until they reach the age of 40, 50 or more.

In conclusion, I feel that (1) testosterone is not a specific for the male climacteric, since estradiol and diethylstilbestrol are equally efficacious in abolishing the vasomotor phenomena; (2) the male climacteric is not a pathologic but a physiologic process; (3) decrease of sexual potency and/or libido is not necessarily related to the male climacteric but may be coincidental; (4) the climacteric in the male is just as physiologic as it is in the female, and (5) testicular failure per se is not necessarily the etiologic factor for the male climacteric. Rather, it is felt to stem from a disturbance of the heat regulating mechanisms of the body resulting from a drop in level of certain steroids.

A. R. ABARBANEL, M.D., Washington, D. C.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, February 10, page 355.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 26-28. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.

ALASKA: Juneau, March. Sec., Dr. W. M. Whitehead, Box 561, Juneau. ARKANSAS: * Eclectic. Little Rock, June 7. Sec., Dr. C. H. Young, 1415 Main St., Little Rock. Medical. Little Rock, June 7-8. Sec., Dr. D. L. Owens, 701 Main St., Little Rock.

CALIFORNIA: Oral. Los Angeles, March 3. Written. Los Angeles, Feb. 27-March 2. Sec., Dr. Frederick N. Scatená, 1020 N St., Sacramento 14.

COLORADO: * Denver, April 3-6. Final date for filing application is March 19. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT: * Homeopathic. Derby, March 12-13. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven. Medical. Examination. March 13-14. Endorsement. March 27. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: Examination. Dover, July 10-12. Reciprocity. Dover, July 17. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: * Reciprocity. Washington, March 12. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

FLORIDA: * Jacksonville, June 25-26. Sec., Dr. Harold D. Van Schaick, 2736 S. W. Seventh Ave., Miami 36.

ILLINOIS: Chicago, April 3-5. Superintendent of Registration, Department of Registration and Education, Mr. Philip Harman, Springfield.

KANSAS: * Topeka, Feb. 19-20. Sec., Board of Medical Registration and Examination, 905 N. Seventh St., Kansas City 10.

KENTUCKY: Louisville, June 18-20. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville 2.

MAINE: Portland, March 13-14. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MARYLAND: Medical. Baltimore, June 19-20. Sec., Dr. J. T. O'Mara, 1215 Cathedral St., Baltimore. Homeopathic. Baltimore, June 19-20. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, March 13-16. Sec., Board of Registration in Medicine, Dr. H. Q. Gallup, 413-F State House, Boston.

MINNESOTA: * Minneapolis, April 17-19. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

MONTANA: Helena, April 2-4. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

NEW HAMPSHIRE: Concord, March 8-9. Sec., Board of Registration in Medicine, Dr. D. G. Smith, 77 Main St., Nashua.

NEW JERSEY: Trenton, June 19-20. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: * Santa Fe, April 9-10. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NORTH DAKOTA: Grand Forks, July 3. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: * Endorsement. Columbus, April. Columbus, June. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * Oklahoma City, June 14-16. Sec., Dr. J. D. Osborn, Jr., Frederick Bldg.

PENNSYLVANIA: April 10-13. Act. Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 358 Education Bldg., Harrisburg.

RHODE ISLAND: * Providence, April 5-6. Chief, Division of Examiners, Mr. Thomas D. Casey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 25-27. Sec., Dr. N. B. Heyward, 1329 Blandina St., Columbia.

TEXAS: Galveston, May 7-9. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

VERMONT: Burlington, June. Sec., Dr. F. J. Lawliss, Richford.

VIRGINIA: * Richmond, June 20-23. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WEST VIRGINIA: Charleston, Feb. 26-28. Commissioner, Public Health Council, Dr. John E. Offner, State Capitol, Charleston 5.

WISCONSIN: * Milwaukee, June 26-28. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

COLORADO: Denver, March 7-8. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

DISTRICT OF COLUMBIA: Washington, April 23-24. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

FLORIDA: DeLand, June 1. Final date for filing application is May 17. Sec., Dr. J. F. Conn, John B. Stetson University, DeLand.

IOWA: Des Moines, April 10. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MICHIGAN: Ann Arbor and Detroit, May 11-12. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

MINNESOTA: Minneapolis, April 3-4. Sec., Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis 14.

NEBRASKA: Omaha, May 1-2. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln.

OKLAHOMA: Oklahoma City, April 9. Sec., Dr. J. D. Osborn, Jr., Frederick Bldg.

OREGON: Portland, March 3. Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.

SOUTH DAKOTA: Yankton, June 19. Sec., Dr. G. M. Evans, Yankton.

TENNESSEE: Memphis, March 27-28. Sec., Dr. O. W. Hyman, 874 Union A. B., Memphis.

WISCONSIN: Madison, April 7. Sec., Professor R. N. Bauer, 152 W. Wisconsin Ave., Room 834, Milwaukee 3.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

14:461-494 (Sept.) 1944

Studies on Incidence and Nature of False Positive Serologic Reactions for Syphilis. C. R. Rein and Elizabeth S. Elsborg.—p. 461.

Simple Rapid Flocculation Slide Test for Trichinosis in Man and in Swine. Hazel Suessenguth and B. S. Kline.—p. 471.

*March Hemoglobinuria: Report of 2 Cases. R. E. Hobbs.—p. 485.

Multiple Malignant Hemangiomas of Liver. G. H. Andries and D. H. Kaump.—p. 489.

March Hemoglobinuria.—Hobbs reports march hemoglobinuria in 2 soldiers aged 20 and 32 respectively. Both passed bloody urine after long, strenuous marches. The appearance of the hemoglobinuria following marching simplifies the diagnosis. The only significant laboratory findings, besides the hemoglobinemia and hemoglobinuria, were the leukocytosis and the change in the albumin-globulin ratio in the first patient. In the second patient only a total protein determination was done, and it was not possible to subject him to another march. Hemoglobinemia was definite in both cases, giving weight to the theory that a general intravascular hemolysis takes place, instead of hemolysis limited only to the renal blood vessels. Attempts were made to show that the erythrocytes in these cases were more susceptible to mechanical trauma by putting half of an oxalated specimen of blood in a Kahn shaker for periods varying from ten to sixty minutes and keeping the other half of the specimen as a control. Both specimens were then centrifuged, and plasma hemoglobin determinations were made. Control specimens were run on 10 normal men and the changes in the plasma hemoglobin values in the 2 patients and the control group were similar. Feigl found by spectroscopic and chemical methods that half of 27 men whom he examined after an army pack march of 35 kilometers had blood pigment in their serum and urine.

14:495-548 (Oct.) 1944

Pathology and Bacteriology of Streptococcus Endocarditis in Relationship to Sulfonamide Chemotherapy. T. R. Hamilton and Bette W. Hamilton.—p. 495.

Pathology and Bacteriology of Streptococcus Endocarditis in Relationship to Sulfonamide Chemotherapy: II. Effect of Temperature Elevation on Action of Sulfathiazole on Endocarditis Strains of Streptococcus Viridans, Enterococci and Group A Streptococci. Bette W. Hamilton and T. R. Hamilton.—p. 502.

*Endocarditis Due to Brucella: Report of 2 Cases. J. D. Call, A. H. Baggenstoss and W. A. Merritt.—p. 508.

Filtrable Infectious Agent Obtained from Alpha Streptococci Isolated in Studies of Case of Poliomyelitis. E. C. Rosenow.—p. 519.

Platelet Count, Bleeding Time, Clotting Time, Capillary Fragility, Prothrombin Concentration and Clot Retraction in Paretics Receiving Therapeutic Malaria. L. W. Diggs.—p. 534.

*Agranulocytosis Following Thiouracil Administration. M. A. Rubinstein.—p. 540.

Pelger-Huët's Familial Nuclear Anomaly of Leukocytes. A. Van Der Sar.—p. 544.

Endocarditis Due to Brucella.—Call and his associates of the Mayo Clinic consider it surprising that reports of cases of endocarditis due to brucellosis are not more numerous in view of the frequency of Brucella infections in the general population, the frequency of prolonged bacteremia and the established fact that previously damaged cardiac valves are vulnerable to invasion by Brucella despite its low virulence. They report the clinical and pathologic aspects of 2 cases observed by them. Among the peculiarities of this type of endocarditis are the tendency to the involvement of the aortic valve, the tendency to ulceration and perforation, and the granulomatous nature of the visceral and neurologic lesions.

Agranulocytosis Following Thiouracil Administration.—Rubinstein reports the history of a woman aged 47 in whom carcinoma of the thyroid had been diagnosed by biopsy and bone metastases by radiologic evidence. After receiving a series of x-ray treatments, the patient was started on thiouracil to observe its effect on the thyroid nodes. The dose used was 0.2 Gm. four times daily. Under the influence of this treatment the thyroid nodes seemed to decrease in size and to become softer, the patient had less pain and the nodes in the supraclavicular area became softer and smaller. She developed a severe agranulocytosis. Serial bone marrow studies demonstrated arrest of maturation associated with hypoplasia of the myeloid elements. Complete hematologic recovery followed discontinuation of the drug. The return to normal of the bone marrow preceded that of the peripheral blood.

American J. Digestive Diseases, Fort Wayne, Ind.

11:381-414 (Dec.) 1944

Infectious Gastroenteritis: Epidemiologic and Laboratory Study. E. C. Rosenow.—p. 381.

*Dietary Factors in Treatment of Cirrhosis Without Jaundice. A. B. Rimmerman, S. O. Schwartz, II, Popper and F. Steigmann.—p. 401.

Studies of Gastric Secretion During Electric Shock Therapy.—D. Fetter.—p. 405.

Effect of Electric Shock Therapy on Muscle Movements. D. Fetter and H. de Jong.—p. 406.

Dietary Factors in Treatment of Hepatic Cirrhosis.—Rimmerman and his associates selected 10 patients with liver cirrhosis for study by means of liver function tests, and the oral hippuric acid excretion tests, the cholesterol/cholesterol ester partition, quantitative urinary and stool urobilinogen excretion, icterus index, nonprotein nitrogen determination, determination of albumin-globulin ratio, the cephalin cholesterol flocculation test and the Takata-Ara reaction were performed. The hematologic work-up consisted of erythrocyte, leukocyte, platelet and reticulocyte counts; hemoglobin, hematocrit and sedimentation rate determinations; differential counts, and examination of the red cells in the smear preparations. In a number of cases marrow examination was also performed. The patients were given a diet containing 6 Gm. of carbohydrate, 2 Gm. of meat free protein and 1 Gm. of fat per kilogram. The average diet contained over 3,000 calories daily. Yeast was given to provide all members of the B complex. Crude liver extract was administered. Choline was given as lecithin, either in the form of a spread on crackers or in cookies. Other vitamins and minerals were given in a milk mixture. The results of the liver function tests indicated definite improvement in a number of cases. The hematologic picture, except for improvement in anemia, did not show changes commensurate with the subjective improvement.

Merit System in Public Health. L. F. Burney and F. M. Hemphill.—p. 1173.

Popular Health Education. A. Massey.—p. 1179.

Intracutaneous versus Subcutaneous Vaccination Against Typhoid.—Luippold shows that the standard subcutaneous course of T. A. B. vaccine consisting of 0.5, 1.0 and 1.0 cc. is more effective in the production of typhoid, paratyphoid A and paratyphoid B protective substances than is one tenth to one fifth of this dosage intracutaneously administered. The standard subcutaneous course of T. A. B. vaccine is more effective in the production of typhoid H and O agglutinins than is one tenth to one fifth of this dosage intracutaneously administered. In small experimental groups there was found no evidence that persistence of agglutinative or protective antibodies at the end of one year is a special attribute of either intracutaneous or subcutaneous administration of T. A. B. vaccine. Although local and systemic reactions are more frequent and pronounced following administration of the standard subcutaneous doses of T. A. B. vaccine than following the intracutaneous

injection of one tenth or one fifth of these doses, the author feels that it is undesirable to risk lowering the protection for the questionable reward of milder reactions. Under the best conditions of immunologic response to artificial immunization the standard method of vaccination cannot be expected to be adequate at all times to the challenge of infecting organisms. Adoption of the intracutaneous administration of reduced doses of T. A. B. vaccine would seem to increase this inadequacy. It is not to be inferred from these conclusions that the intracutaneous administration of T. A. B. vaccine for the establishment of initial immunity is condemned. On the contrary, intracutaneous vaccination has a definite usefulness in its application to the elderly and to allergic persons, in whom severe or serious disturbances may be avoided by the administration of reduced doses, intradermally placed. The author does not consider the standard subcutaneous course of T. A. B. vaccination as the ultimate in antityphoid vaccination procedures. He thinks that intervals between doses, and the doses themselves, would bear investigation.

Early Diagnosis of Pulmonary Tuberculosis.—Mattison selected for study three counties in upstate New York. Two were predominantly rural; the third included a city of about 200,000 population. In addition to the information routinely available from clinic and hospital records, the patients were questioned in detail as to the reasons for their first medical consultation. The time lags were determined between appearance of symptoms and seeking medical care, between the first visit to a physician (for symptoms referable to the chest) and the initial x-ray examination, between that x-ray examination and a definite diagnosis of tuberculosis, and between that diagnosis and reporting of the case to the health department. The observations indicate that case finding among the symptomatic cannot be expected to result in a majority of cases being discovered at a minimal stage; contact examination among associates of diagnosed patients, although yielding a high proportion of early cases, is limited in its scope, especially among urban residents. Mass roentgenography would appear to be needed if substantial reduction of cases which are advanced at the time of discovery is to be achieved.

Effects of Cooling on Experimentally Infected Tissues.

—Bruneau and Heinbecker describe investigations to determine the effects of reduced temperatures on both the local tissue response and the organisms responsible for it, and to determine the eventual course of a local infection as altered by a temporary period of cooling. A concentrated suspension of Streptococcus hemolyticus in broth was used to produce a localized infection. Mongrel dogs weighing from 4 to 8 Kg. were used as experimental animals. The inoculated limbs were then cooled to 6 C. (42.8 F.) for various lengths of time. The control animals were injected in a similar fashion and were placed in

cages at room temperature. The authors found that the exposure of inoculated tissues to a temperature of 6 C. for periods up to ninety-six hours results in a definite inhibition of the usual inflammatory response to Streptococcus hemolyticus. This inhibition is evidenced by the gross and microscopic picture observed after cooling. It is further substantiated by the fact that no significant decrease in the number of organisms injected is observed under these conditions. At room temperature the decrease in the number of bacteria follows a logarithmic curve. Cooling delays the rate of destruction of bacteria in living tissue. Gelatinous edema, vascular congestion and minimal diapedesis were noted throughout the cooled limb, even at a distance from the site of inoculation. The degree of edema seemed related to the length of the cooling period. These changes were also observed in limbs that were cooled without previous inoculation. This would suggest that some of the reactive changes observed in the tissues are due to the effects of cold itself. This edema, with temporary anesthesia and loss of motor function and the occasional appearance of necrotic skin lesions after the return of the limb to a normal environment, bears a striking resemblance to the clinical syndrome of immersion foot. At the site of inoculation the pathologic findings were similar but slightly more severe. The evidence seems to indicate that the application of cold for periods up to four days will not have a beneficial effect on the course of a localized infection. At most, a relative status quo is present as long as the reduced temperature is maintained. However, the diffuse edema argues against regarding this condition as a merely innocuous suspension of bacterial and tissue activity. The authors consider it evident that the clinical application of cold (6 C.) to infected tissue will have no therapeutic value in itself.

Effect of Cooling on Wound Healing.—Large and Heinbecker carried out experiments on dogs to study the effects of prolonged refrigeration on wound healing. They determined the nature of the healing process in clean incised wounds of the skin and subcutaneous tissues of the forelimb after cooling to 6 C. for a period of twenty-four to seventy-two hours, using similar incisions in the opposite limb as controls. The healing process was studied by measurements of the tensile strength and by microscopic examination of the wounds at varying intervals. The results show that during the cooling period there is no reaction on the part of the tissues to the injury inflicted by the incision and that subsequently there is a definite lag in the healing of the wounds, the degree of delay varying with the duration of the cooling period. In wounds treated by delayed suture after cooling for twenty-four or forty-eight hours the incidence of infection is much greater than in control incisions maintained at normal temperatures. The results of these experiments, together with those of Bruneau and Heinbecker, indicate that harmful effects result from prolonged refrigeration of living tissue. It is felt, therefore, that refrigeration anesthesia is not ideal for amputations. If the aim is to diminish absorption from a gangrenous region by local cooling, this can be accomplished by refrigerating the limb below the desired amputation level in order that the anesthesia so induced may permit the application of a tight tourniquet. After restorative measures have been effective, amputation then can be carried out under ordinary anesthesia above the level of cooling without harmful sequelae. It has been suggested that wounds of the extremities incurred on the battlefield be refrigerated during transportation and until proper emergency surgical treatment can be instituted, an interval of many hours or even days. Because of the increased incidence of wound infection after the cooling period shown to occur in the described experiments, it is recommended that wounds sustained on the battlefield should not be treated by refrigeration unless there is no hope of saving the part.

Subtotal Pancreatectomy in Hyperinsulinism.—Brush and McClure say that the criteria for a diagnosis of islet cell adenoma and the indication for operation have been described by Whipple, who stressed that the syndrome is characterized by a triad of nervous system disorders, such as confusion, coma, convulsions and collapse coming on in the fasting state while the blood sugar level is 50 mg. per hundred cubic centimeters or less, and the relief of symptoms by the administration of dextrose. When the blood sugar does not fall to 50 mg. per hundred cubic centimeters during an attack, a search for causes other than islet

adenoma must be made. When the blood sugar during an attack is above 50 mg. per hundred cubic centimeters a diet low in carbohydrate, 50 Gm. or less, and high in protein will often give relief, because while 50 per cent of the protein may yield dextrose this conversion takes place at a slow, even rate and this fact, as well as the slower absorption rate of protein, prevents great elevation of the blood sugar, which would in turn stimulate the pancreas. It has been shown by Conn that the dextrose tolerance curve is influenced by the antecedent diet. A dextrose tolerance test taken after a proper preparatory diet is of diagnostic value in hypoglycemia. Organic and functional hyperinsulinism both give a low dextrose tolerance curve, and the organic cases usually have an abnormally low fasting level. Studies on the utilization of the injected dextrose are especially indicated in borderline cases. The method which the authors have used is that suggested by Johnston of taking a basal metabolic rate prior to injection of dextrose and repeating the metabolism test at thirty minutes, one hour, two and one half hours and three hours after the injection. Urine samples are examined for nitrogen and sugar if the proportion of carbohydrate, fat and protein utilized is to be determined. The calculation from these studies of the respiratory quotient gives diagnostic information and is also of benefit in following the patients postoperatively. These studies may aid in determining the advisability of performing a subtotal pancreatectomy in patients who do not conform exactly to the "Whipple triad" and yet have the symptoms of hyperinsulinism. The authors present the histories of 2 patients with spontaneous hypoglycemia in whom no island tumor could be found. The highly satisfactory results obtained following subtotal resection in these cases make the authors confident that no actual islet tumor existed. They emphasize that a large amount of pancreas must be resected. The removal of a large amount of the pancreas does not seem to cause any subsequent digestive or metabolic disturbance.

Hazards of External Use of Sulfonamide Compounds.

—Abramowitz says that the indiscriminate use of sulfonamides is questionable not only because of the uncertain results but because of the potential hazards that may develop. The innumerable preparations containing sulfonamide compounds, usually sulfathiazole, generally shorten the duration of impetigo, ecthyma, chancroid and possibly other types of primary and secondary pyodermas, but this advantage is offset by the subsequent complications that may appear in these as well as in other dermatoses (eczematous eruptions, varicose ulcers, burns and minor surgical injuries) and minor infections of the mucosal orifices. These complications are: (1) development of a local or generalized dermatitis (allergic sensitization), (2) appearance of photosensitization to sunlight and ultraviolet rays, (3) interference with the action of the roentgen rays, (4) delay in wound healing time, (5) local sanguineous oozing, (6) interference with the action of sulfonamide compounds by local anesthetics of the procaine series and the chemically related vitamin para-aminobenzoic acid, (7) resistance to sulfonamide therapy and (8) rendering the patient vulnerable to the subsequent use of the

drug when most needed. The author believes that reactions from the topical application of the sulfonamide drugs are more frequent than is suspected. Wider dissemination of the knowledge of reactions and their consequences is desirable. Some restrictions should be adopted to prevent the indiscriminate use of sulfonamide ointments and other pharmaceutical forms for external use.

Agranulocytosis Following Mapharsen Therapy.

Kasich reports 2 cases of agranulocytosis, both occurring in Negro soldiers following mapharsen therapy for syphilis. The agranulocytosis in these 2 cases can be ascribed to the mapharsen with a fair degree of certainty. Although idiopathic granulocytopenia has been described, it is unusual. The patients had taken no other drug known to cause granulocytopenia. They had been given five doses of mapharsen in thirteen and twenty-one days and received 0.28 and 0.27 Gm. respectively. The mechanism by which drugs produce agranulocytosis is unknown. Individual susceptibility appears to be the most important factor. Although agranulocytosis seems to be an infrequent complication of mapharsen therapy, frequent leukocyte counts should be made on all patients receiving this drug. The treatment in the reported cases consisted in the administration of sulfadiazine, pentnucleotide and transfusions of citrated blood. Both patients made uneventful recoveries.

Aplastic Anemia, Acute Agranulocytosis and Thrombopenic Purpura Complicating Mapharsen Therapy.

—In the case reported by Freeman a man aged 37 gave a history of having had syphilis for twenty years and of having taken treatments irregularly over a period of two years until January 1943. When treatment was first begun he had several febrile reactions, but thereafter he had tolerated his treatments. Neosarsphenamine was the arsenical employed. In March 1943 the patient entered military service. He was found to have a positive serologic reaction and further therapy was advised. Mapharsen was the arsenical used. On May 18, 1943 the patient first noticed a purpuric eruption on the arms and forearms. He was at that time receiving mapharsen (0.06 Gm. twice weekly) and bismuth subsalicylate weekly. After he received the tenth injection of mapharsen, the purpura appeared, but two more injections of mapharsen were given. The total amount of recent treatment was five injections of the bismuth preparation and twelve of mapharsen. The author saw the patient ten days after the onset of purpura and four days after the last dose of mapharsen had been administered. In view of the history and clinical observations the following diseases were considered after preliminary examination: (1) blood dyscrasia due to mapharsen (arsenical thrombopenia?), (2) infectious mononucleosis, (3) monocytic leukemia and (4) purpura of other origin than that of drug intoxication. The first blood smears indicated that the severe anemia was aplastic, with agranulocytosis. The patient's condition became progressively worse and he died on his ninth day in the hospital, nineteen days after he first noticed his purpura. The etiologic factor in this case is considered to have been the trivalent arsenical. The patient had received bismuth subsalicylate, but he had none of the symptoms of salicylate intoxication. No evidence of infectious mononucleosis or of aleukemic leukemia was found.

Surgical Treatment of Intramedullary Lesion of Spinal Cord.—Woods and Pimenta report 68 consecutive cases of intramedullary lesion of the spinal cord treated surgically. They stress that: 1. The surgical treatment of intramedullary tumors of the cord produces unexpectedly good results when the location and size, and often the infiltrative character, of these neo-

plasmas are taken into consideration 2. The comparatively slow growth of these tumors offers promise of better results in the future, with the attainment of early diagnosis and with surgical intervention before irreversible damage to the spinal cord has occurred. 3. The best surgical results are obtained when the tumor can be totally excised without damage to the cord. If this is not possible because of lack of demarcation, decompressive vertical incision of the posterior surface of the cord over the entire extent of the tumor should be attempted. The concept that an intramedullary tumor encountered at operation is inoperable and is best left alone, or only a specimen taken for biopsy, is unjustifiable. 4. Intensive roentgen therapy following operation appears to be of benefit with certain gliomas of the spinal cord. 5. Ependymoma, because of its frequent demarcation and the apparent limitation of its growth, offers a better prognosis than the more invasive gliomas. 6. Intramedullary dermoid, because of its slow growth and encapsulation, lends itself either to total or to partial excision. 7. The surgical treatment of syringomyelia, with or without roentgen therapy, has not produced the hopeful results previously reported in the literature.

Continuous Spinal Anesthesia.—Spinal anesthesia has been used in the Middlesex Hospital in Middletown, Conn., in 8,197 cases. Six thousand of these cases, according to Magnano were done under "one dose" spinal anesthesia and 2,197 cases under continuous spinal anesthesia. In the first 1,000 cases the operation was begun and finished under spinal anesthesia, but in the longer procedures the spinal anesthesia had to be supplemented by administration of pentothal sodium. The oldest patient in this group was 90 years, the youngest 15 days. A subtotal gastrectomy required six hours of anesthesia. The shortest procedure, incision and drainage of an abscess, took about five minutes. The former case required 1,100 mg. of procaine hydrochloride and the latter 50 mg. In 406 appendectomies the average dose of procaine used was 157 mg. The minimum dose was 75 mg. and the maximum dose was 500 mg. The weight of the patient does not determine the dose of procaine hydrochloride necessary. In 51 cholecystectomies the average dose of procaine administered was 283 mg. As a rule more procaine is required for work in the upper abdomen than in the lower abdomen. Seventy-six cesarean sections were done under continuous spinal anesthesia. The author gives these reasons for regarding this method as the anesthetic of choice in cesarean operations: 1. The mother alone gets the anesthesia and the fetus is not affected. 2. The anesthetic can be withdrawn if the patient shows signs of toxicity. 3. The abdominal muscles are relaxed. 4. The intestine is contracted. 5. The child cries immediately after delivery. 6. The uterus contracts well after delivery because the nerve control of the uterus is not blocked. There were 118 gynecologic operations, 69 herniorrhaphies, 68 orthopedic operations, 36 hemorrhoidectomies, 14 pilonidal cyst operations, 11 prostatectomies and others. The blood pressure showed less fluctuation than in the one dose method of spinal anesthesia. The dosage can be individualized in this method, and the drug can be changed if necessary. He believes that this method of spinal anesthesia is safer and more controllable than the one dose method.

Total Esophagectomy in Cancer of Esophagus.—Vasconcelos describes and illustrates in detail a new technique for total esophagectomy. Peridural is preferred to general anesthesia. The operation consists of an abdominal, a thoracic and a cervical stage. A preliminary artificial pneumothorax is established in the interval between the abdominal and the thoracic stage. This is considered to be an essential preparation before opening the thorax. In the opinion of the author this new technique completely alters the prognosis of total extirpation of the esophagus and permits a more optimistic attitude because of the reduction in complications and mortality rate.

Allergic Conditions and Ascorbic Acid.—Newbold attempted to investigate the question whether massive doses of ascorbic acid given orally would have an effect on the skin test in a definite allergic condition regardless of the deficiency or the adequacy of the vitamin in the subject. The plasma levels of ascorbic acid were determined by the Mindlin-Butler method in most cases. The 8 subjects were young men who had suffered from periodic attacks of hay fever since childhood. A total of forty-three control skin tests were made on these subjects with an extract of short ragweed. The tests were not made during an active period of hay fever. The plasma levels of ascorbic acid were measured at the time of most skin testing. At various intervals large amounts of ascorbic acid were given over a period of several days, and more skin tests were made. The plasma level of ascorbic acid was likewise measured as previously. The average diameters of the erythemas of the two sets of data were compared. There was no evidence that ascorbic acid had any significant effect on allergic skin reactions caused by intracutaneous injection of an extract of short ragweed pollen. It is realized that the experiment in itself cannot entirely prove that ascorbic acid can have no clinical value.

 *Stab Wound of Heart: Report of Successful Repair of Laceration of Left Auricle. L. L. Thompson Jr.—p. 218.

Successful Repair of Laceration of Left Auricle.—A soldier aged 25 was admitted to the hospital with a history of having been accidentally stabbed in the left side of the chest about an hour previously with a pocket knife. The wound was 2 cm. lateral and 2 cm. inferior to the left nipple in the fifth interspace and was sucking in character. The patient was given 2 units of blood plasma, the wound of entrance was excised and the heart was exposed. In the pleural cavity a number of large clots were seen lying against the medial aspect of the left lung. There was approximately 400 cc. of noncoagulated blood in the cavity. A laceration, not readily apparent, about 1.5 cm. in size was found in the superolateral aspect of the anterior pericardium. The laceration was enlarged and one of equal size was found

completely penetrating the wall of the left atrium. With some difficulty the auricular wound was closed with three interrupted sutures. At the moment of completion of the auricular suture respiration stopped and the ventricular contractions became quite slow and irregular. On initiation of artificial respiration by the anesthetist and injection into the myocardium of the right ventricle of 0.5 cc. of 1:1,000 epinephrine solution respiration started and the heart began to contract regularly. The convalescence was complicated by a pulmonary infection. Thompson reports that electrocardiographic changes indicative of pericarditis are evident two months postoperatively, although clinically the patient has recovered.

*Fluoride Domestic Waters and Systemic Effects: I. Relation to Bone Fracture Experience, Height and Weight of High School Boys and Young Selectees of Armed Forces of United States. F. J. McClure.—p. 1543.

Fluoride Waters and Systemic Effects.—McClure studied the skeletal effects of dietary fluorine on the height, body weight and bone fracture experience in selected groups of 1,458 high school boys and 2,529 young men taking the physical examination at United States armed forces induction centers. The significance of these studies relates to two facts: (a) Many drinking waters in the United States and other parts of the world contain fluorides; (b) it has been suggested that optimum quantities of fluoride might be added to domestic water supplies or directly to children's diets for the partial control of dental caries. The number of fractures per hundred among high school boys varied from 21.3 to 32.4. There was no relation of fracture experience to fluoride exposure. The height-weight data were not related to fluoride exposures. The bone fracture experience of young men varied from about 25 to 30 fractures per hundred men averaging about 18 to 25 years of age. An experience of more than 1 fracture varied from 1.7 to 4.8 men per hundred men. These data on bone fracture experience for both men and boys suggest strongly that no serious impairment in skeletal performance, as might be manifest in number of broken bones, seems related to exposure to fluoride domestic waters of the concentrations studied in this survey. Texas men exposed to highest water-fluorine concentrations and Oklahoma men averaged 69.6 and 69.4 inches in height (weight 149.0 and 142.4 pounds), respectively. Men from rural Indiana and Indianapolis averaged 68.1 and 68.3 inches in height, 146.8 and 146.2 pounds in weight, respectively. Washington, D. C., men averaged 69.3 inches and weighed 151.2 pounds on the average. New Hampshire men were 67.3 inches tall and weighed 149.6 pounds on the average. These height-weight figures showed no relation to fluoride exposure.

New Plan in Treatment of Hyperthyroidism.—Twenty patients with severe hyperthyroidism were treated by Rea with a combination of intravenous pentothal, spinal and inhalation anesthesia. The purpose of the spinal anesthesia was to inhibit medullary adrenal releases during the operation and thus to

forestall the occurrence of an immediate severe postoperative reaction. It is not intended to secure anesthesia to a level which would permit the operation being done under this agency alone. The adrenals are important, as suggested by the reactions accompanying the so-called Goetsch test. If there were signs of hyperadrenalism, one would expect an increase in the blood sugar. Examination of the blood sugar did not reveal any increase, probably because of the short time factor in performing the operation. No accurate method for the determination of epinephrine in the blood is available. A somatic analgesia to about the fourth dorsal segment must be derived from the use of spinal anesthesia if one hopes to inhibit the splanchnic nerves to the adrenal glands. Procaine hydrochloride was used as a spinal anesthetic, the dose varying from 80 to 120 mg. The head of the table may be tilted downward 10 degrees for a few minutes to assure high enough anesthesia. In so doing the patient's head should be raised on a pillow to prevent the anesthesia from extending to the cervical segments. No pressure drugs have been used to prevent or treat falling pressure. When it fell greatly, the Trendelenburg position and intravenous fluid were used. It is not necessary to use spinal anesthesia for all thyroid patients.

Malignant Goiter.—Ward stresses the importance of knowing which types of goiter are likely to become malignant and which signs should arouse suspicion of malignant change. Cancer is almost unknown in exophthalmic goiter. In the author's series of 5,439 thyroidectomies there were 168 cases of cancer. Only 1 of these occurred in the exophthalmic type. Almost all malignant goiters are nodular. The incidence of malignant goiter is influenced by the degree of endemicity and the frequency of nodular goiter in a given geographic locality. The preponderance of malignant goiter is in favor of women; but the expectancy for carcinoma in men with nodular goiter is much greater, 1 in 9 men coming to surgery. Of the three cardinal signs of malignant goiter—hoarseness, fixation and hardness—at least the first two denote a far advanced lesion. Any or all of these signs can be produced by benign growths. Carcinomatous and calcareous degeneration may occur in the same nodule, and delay in removing it alters the prognosis unfavorably. Long standing or slowly growing tumors which suddenly undergo rapid growth and produce pressure symptoms are suggestive and should be extirpated before the clinical picture of malignancy develops. The author has found it practical from a prognostic and therapeutic point of view to classify malignant thyroid tumors according to their characteristics of growth and their microscopic architecture. He differentiates three groups: papillary carcinomas, malignant adenomas and all others. Prognosis is based on the time of diagnosis, the pathologic pattern and the presence of metastasis. Deaths are in direct proportion to the ease of diagnosis. Papillary carcinoma offers the best prognosis, and the degree of malignancy can apparently be estimated by the corresponding extent of departure from the papillary pattern. The prognostic evaluation of metastasis is similar to that in carcinoma of other organs, with the exception of rare dormant metastatic lesions in patients seemingly well years after operation and irradiation. Prophylaxis consists in the removal of nodular goiter so early that there is no preoperative suspicion of malignant change. Statistics of 1 carcinoma in 9 men and 1 in 21 women operated on for nodular goiter substantiate the importance of this procedure. Suspected or diagnosed carcinoma calls for radical resection, always preserving at least one recurrent nerve, one parathyroid gland and both carotid arteries. Roentgen therapy can be used alone or in combination with surgery but should never be administered without the benefit of a biopsy report. Results may be expected to be good in the extremely radiosensitive papillary carcinomas, fair in a small number of malignant adenomas and unfavorable in all others. The principal value of x-ray therapy lies in its administration postoperatively.

Need for Asepsis in Local Penicillin Therapy.—McKissock and his associates point out that gram negative organisms have been found in the discharge from penicillin treated wounds. Organisms like *Escherichia coli*, *Proteus vulgaris* and *Pseudomonas aeruginosa* have been grown from the aspirate from wounds receiving local injections of penicillin solution. The time at which such gram negative organisms gain entry to the wound is important. The suggestion has been made that they are present in the wound initially but are overgrown by staphylococci and streptococci in first cultures, and only when the latter organisms have been removed or inhibited by penicillin can the gram negative organisms be obtained in culture mediums. The authors are inclined to think that the appearance of these gram negative organisms in a postoperative wound is due to added hospital infection. The opportunity for cross infection of a wound undergoing treatment with penicillin is particularly good. A rubber tube runs from the outside air to the depths of the wound, and through this channel injections of the penicillin solution are made, usually twice daily, for from three to five days. Unless unusual precautions are taken to safeguard this channel against bacterial contamination, it is easy to imagine the common fecal organisms (which are penicillin resistant) being carried into the wound at the time of injection. The authors undertook experiments to see whether these organisms need necessarily appear in penicillin treated wounds or whether they could be excluded by methods designed to close the supposed new port of entry (the penicillin tube) and by the other precautions against hospital infection of wounds. They report observations on two series of battle casualties, each comprising 20 men, in which local penicillin therapy was employed. The incidence of potential cross infection was 3 cases in 20 in the unit's original surroundings, and no clinical cross infection occurred. In the second series, under less perfect conditions, the potential rate rose to 7 cases in 20, and 1 superficial case of clinical hospital infection resulted. Cross infection of wounds by way of the penicillin tube is an obvious possibility and, as it has not appeared in the present series (the 1 case described being only a superficial cutaneous infection), it is suggested that the aseptic screw cap in use is the responsible factor in prevention. The need for proper closure of the scalp wound and very early skin healing is emphasized in view of the total average hospital (or cross) infection rate of 25 per cent.

Liver Necrosis in Burns Treated with Tannic Acid.—Jackson described the results of postmortem examinations on 8 soldiers who died from burns at an Australian general hospital in New Guinea. All burns were first degree flash burns. The cases were comparable, except for the local treatment of the burns; some patients were treated with tannic acid and some were not. Only slight liver damage was observed in the 4 patients who had no coagulant applied to their burns. Similar slight damage was seen in 1 patient whose burns were treated with silver nitrate. One patient had tannic acid alone applied to his burns; in his liver cloudy swelling was the only abnormality found, and he died from a secondary pulmonary infection. Two patients were treated with a mixture of 10 per cent tannic acid solution and 10 per cent silver nitrate solution; at necropsy pronounced hepatic necrosis was found in both. The difference between these 2 livers and the other 6 was striking. From the evidence the author considers it justified in blaming the silver nitrate and the tannic acid for the hepatic necrosis.

Goat for Preparation of Vaccine Against Typhus.—Sergent and Horrenberger point out that search for an abundant source of rickettsias is at the base of the technics of preparation of various nonliving antityphus vaccines. The utilization of rickettsias derived from the lungs of inoculated animals constituted a great advance. In April 1942 at the Pasteur Institute of Algeria the use of goats or sheep was envisaged for the preparation of antityphus vaccine. First, sheep were utilized and it was found that this readily available and easily manageable animal permitted the preparation of large quantities of vaccine. The lungs of goats inoculated with rickettsias constituted an even more advantageous source of virus than did the lungs of sheep: the yield of rickettsias was as great as that of the lungs of mice and it was possible to infect the goat from the mouse. The author mentions measures that have been taken to reduce the frequency and gravity of typhus infections among the laboratory personnel. As a result of these measures, during the last two years only 3 out of 30 persons have contracted a mild form of typhus.

- *Alcoholic Intoxication of Newborn Infants: Case. O. Gonzaga.—p. 163.
Alcoholic Intoxication of Newborn Infant.—Gonzaga advises against the use of alcohol on the breasts of nursing mothers as a disinfectant. He reports the case of a normal infant who developed exaggerated somnolence on the ninth day of his existence. Put to the breast, he sucked with avidity, after which he sank into deep sleep. On the following days he had profuse vomiting. On the thirteenth day he developed torpor, cried and belched. The mother had mumps on the ninth day after parturition. Breast prophylaxis was made with alcohol. The infant's symptoms rapidly improved on discontinuation of alcohol applications to the nipples. The possibility of a nervous manifestation of mumps in the infant was not considered because of the rapidity with which the discontinuation of the use of alcohol by the mother changed the clinical symptom.

Book Notices

Surgical Disorders of the Chest: Diagnosis and Treatment. By J. E. Donaldson, B.S., M.D., F.A.C.S., Major, Medical Corps, Army of the United States. Cloth. Price, \$6.50. Pp. 364, with 127 illustrations. Philadelphia: Lea & Febiger, 1944.

This book is written primarily to acquaint the general practitioner and surgeon with the many changes which in recent years have occurred in the diagnosis and treatment of thoracic disease; changes which have been so rapid that textbooks of a few years ago are now obsolete and so extensive and technical that thoracic surgery as a specialty has acquired great prominence. The author, however, believes that many of the disorders of the chest may safely remain in the hands of the well informed practitioner and general surgeon, while the highly technical operations on the lungs, thoracic wall, heart and other parts require special training and experience. The abnormalities of the thoracic cage and open and closed wounds, including those of war, are considered, with discussion of vital capacity, mediastinal flutter, paradoxical respiration and blast injury. Besides a description of the various diseases of the pleurae, lungs, heart, esophagus and great vessels, the disorders of the mediastinum, diaphragmatic hernia, subphrenic abscess and even the scalenus anticus syndrome are discussed. The technic of delineating the bronchial tree, of the various forms of collapse therapy and of pneumotomy, lobectomy and pneumonectomy are given, with proper indication, in considerable detail.

A terminal section deals with artificial respiration, resuscitation inhalation therapy, anesthesia and physiologic connotations. The author evidently uses pressure anesthesia by mask rather than intratracheal tube. In the statement that "respiratory" arrest for four or five minutes is fatal, "cardiac" arrest may have been intended. Recovery after cessation of circulation in the brain up to seven minutes has been known to occur.

In general the author has given a rather concise but comprehensive and up to date description of the disorders of the chest. Where two different methods of treatment are in use they are described without partiality. The reader is advised as to procedures now discarded or rarely used. At the end of each chapter there is a useful bibliography carried well into 1944. This is the best handbook on thoracic surgery yet published.

The Urinary Tract: A Handbook of Roentgen Diagnosis. By H. Dabney Kerr, M.D., Professor of Radiology, State University of Iowa College of Medicine, Iowa City, and Carl L. Gillies, M.D., Associate Professor of Radiology, State University of Iowa College of Medicine. Cloth. Price, \$5.50. Pp. 320, with illustrations. Chicago: Year Book Publishers, Inc., 1944.

As might be expected from the roentgenologists associated with the urologic clinic at the State University of Iowa Hospitals, the authors have given a splendid exposition of the roentgen diagnosis of the urinary tract in this handbook. The book has an attractive format. It is clearly illustrated, a circumstance which is probably due in no small part to the fact that the authors did the photographic work themselves and were thus able to bring out distinctly the film features which they wished to show. The size of the structures pictured has been kept to a uniform proportion of that of the shadow on the original film throughout so that, in studying them, no allowance need be made for varying sizes in different cuts. All of them (some 475 are given on 306 pages) are quite typical, so that a reasonably well versed urologist was able in most instances to pick up readily the diagnosis from the illustration without referring to the legend; the process in reverse, studying the subject without previous knowledge of it, should be correspondingly easy. The arrangement of putting the illustrations on the right hand page and the legends on the opposite left one facilitates study. The text has been kept to a minimum, reliance being placed on comprehensive legends, which include ample clinical data, and clear illustrations for description and explanation. The sections on the kidneys, ureters and bladder follow conventional lines and are complete. The various types of back flow in the kidney and the diagnostic pitfalls that spring from them are well treated. Similar artefacts arising from too energetic efforts to obtain a ureterogram through a catheter placed against an impacted stone in the ureter are not shown.

A fair criticism of the book is that renal injuries from physical violence have not been dealt with extensively. At present such lesions are common and their study by pyelogram gives important indications for treatment. Likewise, borderline cases that plague both the urologist and the roentgenologist have been omitted. The seventy-four pages, almost one fourth of the book, devoted to the roentgenology of the urethra will be a revelation to those who have not already given attention to the x-ray study of this part. Lesions already known from other angles, the urethroscope, operation and necropsy will be viewed from a new aspect and a wider understanding of their pathologic implications found. This is especially true of study of the prostatic urethra. If this method is applied, lesions that are perhaps not even suspected from the history and clinical examination may be disclosed and indications as to adequate treatment obtained.

Perhaps the most significant sentence of the book is found in the second paragraph of the preface: "We wish to emphasize, therefore, that in determining the status of the urinary tract it is necessary to correlate all clinical and laboratory data with the roentgen data before arriving at a final diagnosis." While this is trite, its substance is all too frequently forgotten by many physicians, and the roentgenologist is often asked to reach a conclusion that can be attained only by collaboration with the urologist. This feature becomes only too evident when a urologist who has been used to such cooperation is asked to work in a situation where the roentgenologic assistance is given grudgingly or stingily or where cooperation is absent altogether. This generally comes from a lack of appreciation of the pathologic and diagnostic problems involved or of ignorance of the limitations of each method of examination. The roentgenologist must know a great deal of urologic pathology and methods in order to help the urologist efficiently.

The book is recommended for all whose interest in roentgenologic urology is more than casual, and it should be in the hands of every teacher and student who is really interested in either branch.

Trichinosis. By Sylvester E. Gould, M.D., D.Sc., Pathologist and Director of Laboratories, Eloise Hospital, Eloise, Michigan. Cloth. Price, \$5. Pp. 356, with 128 illustrations. Springfield, Illinois: Charles C Thomas, 1945.

The author in thirteen chapters has completed a book on a disease which is of paramount importance to the public health in this and other countries. The book is generously and well illustrated and has important and complete data on the epidemiology, immunology, diagnosis, treatment, prognosis and control of trichinosis. Therefore it should prove essential to the libraries of health departments, hospitals, the thoughtful and careful clinician and all purveyors of foods, especially pork products. Gould clearly demonstrates that the main sources of this disease are the communities offering unsafe foodstuffs for feeding pigs and failure to provide proper regulations to make pork and its products safe. The hog industry must from this book become conscious that the production of pork food products is not a private enterprise but carries many obligations within the industry in the interest of the public health. Pork, after all, is an excellent food, and the use of trichinella free meat, at least in sausage, appears necessary and fundamental. This book is a logical, concise, comprehensive and thorough approach to all the characteristics of trichinosis as a disease and public health problem. Its timely publication is certain to prove of value to many workers.

Manual of Urology. By R. M. LeComte, M.D., F.A.C.S., Professor of Urology, Georgetown University, Washington, D. C. Third edition. Fabrikoid. Price, \$4. Pp. 305, with 60 illustrations. Baltimore: William Wood & Company, 1944.

This is a small handbook of eleven chapters, the first three of which discuss the various methods of examination in urology, the symptoms observed in urologic diseases and methods of treatment. The remaining eight chapters discuss briefly the various diseases of genitourinary organs. In this edition is a new section on pain. Recent developments of chemotherapy in the treatment of genitourinary infections and new methods in the treatment of advanced prostatic cancer are included. This book, because of its conciseness, will no doubt continue to be popular with medical students.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TREATMENT METHODS FOR ALCOHOLISM

To the Editor:—I have a patient addicted to alcohol who has, as long as he is sober, the best intentions to abstain from alcohol. As in most such cases, he is unable to do so. Have any promising treatments been developed? I have read about a psychoanalytic treatment that takes about eight days but cannot recall any details. Expense would be no object in this instance.

M.D., Alabama.

ANSWER.—As yet no specific treatment of alcohol addiction has been found. The question as to which of the existing technics should be utilized must depend on a thorough psychiatric study and a complete physical examination of the patient. Gastric and circulatory disturbances and deficiency diseases often attendant on alcoholism should be taken care of as a first consideration.

1. The conditioned reflex treatment has received much attention in the past few years. This technic is a scientific refinement of the old "aversion" treatments. Emetine is being used in preference to apomorphine as the conditioning drug. The treatment requires eight to ten days' hospitalization and reinforcement treatments approximately every three months in the first year. This method has been widely tested and reported on (Lemere, F.; Voegtlin, W. L.; Broz, W. R.; O'Hollaren, P., and Tupper, N. E.: *THE JOURNAL*, Sept. 26, 1942, p. 269. Thimann, J.: *New England J. Med.* 228:333 [March 18] 1943. Kant, F.: *Quart. J. Stud. on Alcohol* 5:229 [Sept.] 1944). The conditioned reflex treatment requires less time than most of the other treatment methods, but according to physicians with experience in this technic it is successful only in the absence of any definite psychopathy.

2. A more recent technic uses hypnosis instead of drugs for establishing the conditioned reflex (Kroger, W. S.: *THE JOURNAL*, Oct. 31, 1942, p. 714). Hypnoanalysis of brief duration is carried out in conjunction with this treatment. Evidently the reference in the query to "psychoanalytic treatment that will take eight days" refers to this technic. This new method has not been tested widely as yet.

3. Electric shock, much used in the therapy of psychoses, has been applied also to the treatment of addiction to alcohol. Success has been reported in the treatment of delirium tremens (Berkwitz, N. J.: *Am. J. Psychiat.* 99:364 [Nov.] 1942), but failure has been reported in alcoholism without psychosis (Neymann, C. A.; Urse, V. G.; Madden, J. J., and Countryman, M. A.: *J. Nerv. & Ment. Dis.* 98:618 [Dec.] 1943). An evaluation cannot be made at this time.

4. The activities of Alcoholics Anonymous, an informal organization of ex-alcoholic addicts, are being observed with interest in the psychiatric literature. They are described in *Alcoholics Anonymous*, published by the Works Publishing Company, New York, 1944. Local organizations in the larger cities of the United States aggregate a membership of approximately 15,000 ex-alcoholic addicts. Psychiatric studies of this group have been made. (Tiebout, H. M.: *Am. J. Psychiat.* 100:468 [Jan.] 1944. McMahan, H. G.: *Illinois Psychiat. J.* 2:15, 1942. Corwin, E. H. L., and Cunningham, E. V.: *Quart. J. Stud. on Alcohol* 5:9 [March] 1944). The usefulness of the social therapy of Alcoholics Anonymous is generally recognized, but there are differences of opinion concerning its limitations.

5. Psychotherapy in one form or another is still the most frequently applied treatment of addiction to alcohol and formally or informally enters into all of the treatments mentioned. At the same time some adjuvant medical treatment is used by nearly all psychotherapists.

DISTANCE OF PROJECTILE VOMITING

To the Editor:—What distance in feet can a patient vomit in projectile vomiting? Are there any records of a patient vomiting 20 feet or more in this condition?

Major, M. C., A. U. S.

ANSWER.—As far as can be learned, this is one event for which national or international records have not been kept. The championship has yet to be determined. Perhaps 20 feet is a little far unless somebody was trying for a record. More than 20 feet down has been observed many times; 20 feet upward or horizontally is another matter!

TYPHOID CARRIERS

To the Editor:—I should like information on the treatment of a white woman, aged 52, who is a confirmed typhoid carrier, apparently healthy except for a psychosis which necessitated her recent commitment to a mental institution. Is the removal of the gallbladder indicated as an accepted procedure? If so, what is the percentage of recoveries, and how long after the operation can the culture be expected to become negative? Are sulfonamides indicated, and how effective are they? Is complete isolation from other patients in the wards or in the day room necessary?

M.D., Michigan.

ANSWER.—Removal of the gallbladder is not an accepted procedure to rid carriers of typhoid bacilli. Such an operation would, no doubt, be successful if the gallbladder were the only place where bacilli propagate, but the probabilities are that they also reside in the liver, in the lymphoid tissues of the intestine and elsewhere. Reports of success have been published after cholecystectomy, but adequate follow-up cultures of feces and urine have seldom been made. Bacilli are often shed in "showers," with perhaps long periods in which the stools or urine are free of them, so that cultures to determine their presence or absence must be made repeatedly over long periods. To answer the second question, if the gallbladder were the only source, and if it was removed, typhoid bacilli should disappear promptly. The sulfonamide compounds are without value in this field, and penicillin will be likely to fail also. Reports are not available on the value of other antibiotics which affect gram negative bacilli. If the patient's psychosis is such that she will not cooperate in the proper disposal of her feces and urine and in other hygienic measures, complete isolation is necessary. With cooperation and obedience, however, the danger of transmitting bacilli to others is minimal, and isolation is unnecessary. The patient should not be permitted to handle food or drink for others.

PAINS IN ARMS DURING LATE PREGNANCY

To the Editor:—During the past several years I have seen maternity patients in the later months of pregnancy who complain of pains in the arms, hands and fingers, which are particularly noticeable at night and are accompanied by a slight swelling of the hands and fingers. These pains are relieved by massage or by getting up and moving about and are severe enough to keep the patient awake at night. The blood calcium is normal, and there seems to be no evidence of vitamin deficiency, for relief is not obtained by the administration of either. The pains are of such severity that it is necessary to give narcotics occasionally. These patients do not suffer from any evident toxemia.

O. G. Mills, M.B., Oshawa, Ont.

ANSWER.—There has been no adequate explanation for the symptoms and findings which are described in this query. It is possible that the altered fluid balance in pregnancy which results in an increase in all tissue fluids may explain some of the symptoms. A decrease in the intake of electrolytes, particularly salt, may help an occasional patient. Heat in the form of a warm bath may offer temporary relief. A small dose of a barbiturate may help some patients. The administration of vitamins and calcium is of no value.

X-RAYS AND BONE UNION

To the Editor:—Has it ever been demonstrated that frequent x-rays have a tendency to delay union in fractured bones?

M.D., Connecticut.

ANSWER.—In a long experience frequent x-ray exposure, that is, diagnostic exposure, has never been found to cause any delay in the union of fractures. By frequent exposure is meant two or three times a week during the first week, once a week for the next three or four weeks and then occasional films. There is undoubtedly a difference between the effect of the rays on infants and children. During the growing period of bones they are more susceptible to the rays than are the adult bones. On the other hand, large doses of x-rays cause aseptic necrosis; this is not uncommon.

ANTICOAGULANT TO FACILITATE INTRAVENOUS THERAPY

To the Editor:—A correspondent in *Queries and Minor Notes* in *The Journal*, Oct. 21, 1944, inquires whether anticoagulants have been used to prevent clotting when pentothal and other solutions are administered intravenously. For the last year I have added 2.5 per cent sodium citrate solution to 2.5 per cent sodium pentothal solution, using not more than 5 cc. of citrate solution to 50 cc. of pentothal. This has been effective in preventing clots forming in the needle when pentothal is administered intermittently for longer anesthetics. No symptoms have been observed from the citrate. It is understood that this represents my personal opinion and is not to be construed as reflecting the policy of the Medical Department of the Army.

DISABILITY ARISING FROM CLOSED HEAD INJURY

DEREK DENNY-BROWN, M.B.

BOSTON

The relationship between the degree of initial traumatic damage done to the cranium in head injury and the extent of subsequent symptoms directly related to bony injury is usually well defined. For example, the part played by a fracture through the orbit in causing subsequent displacement of the globe of the eye, or by a compound or depressed fracture of the skull in causing a hemiplegia of the opposite side, or jacksonian epilepsy, may be clear. Greater difficulty is encountered in forming an estimate of the degree to which these and less direct physical effects account for disability from a previous head injury. Even more obscure is the relationship of such physical after-effects to more general and less tangible symptoms such as headache and dizziness, intellectual deficit, psychoneurotic states, and changes in character and personality which are frequently associated with disability.

Russell,¹ in an analysis of 200 cases of civilian head injury, indicated the importance of the age over 50 years and of long duration of loss of consciousness after injury in increasing the incidence and duration of disability. In a series of cases of war head injuries Denny-Brown² and Symonds and Russell³ have stressed the influence of prolonged unconsciousness and of the presence of mental symptoms in leading to unfavorable ultimate prognosis. It has been suggested by some⁴ that the after-effects of war head injuries differ from those seen in civilian practice, particularly in the psychiatric aspects of disability. Lewis,⁵ in comparing a series of cases of post-traumatic states with simple anxiety states in soldiers, found no essential psychiatric difference between the two. It has often been assumed that post-traumatic mental symptoms in civilians are solely related

to questions of compensation, but Russell⁶ found nervousness in 34 per cent of 72 civilian cases in which no factor of compensation was involved. Greenwood⁷ recently reported a follow-up of cases of civilian head injury and found headache the most common sequel. Seventy-seven per cent of 81 patients followed from the acute stage onward suffered from neurotic symptoms. In three fourths of these, problems of compensation were prominent. In small groups followed for periods up to five years he found that approximately 50 per cent still suffered from symptoms, most frequently headache, dizziness, nervousness and fatigue. He noted no correlation of length of coma, the presence or absence of fracture or of blood in the spinal fluid with subsequent disability. Schaller⁸ attempted to separate two post-traumatic syndromes, a "post-traumatic psychoneurotic state" and a "post-traumatic concussion state" on a basis of no appreciable period of unconsciousness in the former, associated with hysterical exaggeration in statement and behavior, disinclination to work, headache, and favorable effects of settlement of compensation. The "post-traumatic concussion state" followed prolonged loss of consciousness and exhibited predominantly personality change and mental retardation. I² have taken exception to such a division on the grounds that most cases in general experience fall between these two extremes. Symonds,⁹ on the other hand, has long maintained that patients who have suffered a very severe injury may develop psychoneurotic symptoms, and this is certainly true in war injuries.² Further data on disability from head injury in general, particularly on the interrelation of physical and psychiatric aspects, is therefore desirable.

Much of the difficulty of these questions arises in making an estimate of severity of any given head injury. This is derived from the lack of homogeneity in the pathologic changes underlying the condition. Trauma to the head may lead to concussion, simple or compound fracture, laceration of the meninges or of the cranial nerves, contusion of the brain, epidural or subdural effusions or rupture of venous sinuses. There may be any combination of these. Further, the methods of clinical diagnosis at present available do not offer any clear separation of these clinical entities, particularly when they are mild in degree or when more than one is present. Thus it has been common practice to label a state of brief loss of consciousness following head

This work was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the President and Fellows of Harvard College.

From the Neurological Unit, Boston City Hospital, and the Department of Neurology, Harvard Medical School. This report is one aspect of the results of an investigation in which Drs. H. Houston Merritt, Harry L. Kozol, Alexandra Adler, Charles Brenner, Edwin M. Cole and Arnold Friedman took part and, for part of the period, Drs. Jurgen Ruesch and Burness E. Moore.

injury without other signs as concussion. If the spinal fluid is blood stained the condition, otherwise similar, is called "cerebral laceration" or, if the cerebrospinal fluid pressure is raised, "cerebral edema" (Munro¹⁰). Yet it is manifestly possible that the loss of consciousness may then be identical with that called concussion. Alternatively, cerebral laceration or contusion can occur without loss of consciousness. Similarly a patient may die from meningitis for which the path of entry of organisms was a fracture not demonstrable clinically. The cerebrospinal fluid pressure may be raised as a result of sinus thrombosis or obstruction by fracture without cerebral edema. The clinical diagnoses in common usage must therefore be regarded as approximations which are in many ways unsatisfactory. These defects are even more clearly evident when it is sought to argue from diagnosis to prognosis.

The "severity" of an injury furthermore may have different connotations. Pilcher and Angelucci¹¹ have recently made a close analysis of the hospital course of 373 cases of civilian head injury and found fever, respiratory abnormality, compound fracture, positive neurologic signs, coma and bloody spinal fluid to be signs of grave immediate prognostic significance. The immediate surgical gravity of head injury, however, may have no relationship to the ultimate severity of disability. In the following analysis an attempt is made to relate all features of the head injury to disability. In order to do this it was necessary to follow a series of cases from admission to the hospital onward and take account of all possible factors in the injury, the personality and the environment.

MATERIAL

Over a period of eighteen months extending from July 1942 to December 1943, 430 cases of head injury admitted to Boston City Hospital were examined by a team of investigators including neurologists, psychiatrists, a psychometrist and a social worker. Data were obtained on admission, in many cases on the accident floor, and at intervals thereafter including attendance at a follow-up clinic established for the purpose. For the purpose of the present report patients under the age of 15 years and over the age of 55 years were omitted in order to exclude the influence of age as far as possible and to concentrate on groups in regular employment. Chronic alcoholic addicts and vagrants and others who could not be followed were also excluded.

A group of 200 cases followed until symptom free and returned to full employment,¹² or until symptoms had persisted at least six months, remained after the aforementioned eliminations. This group was evenly distributed through the age range 15-54 years (table 1) and comprised 125 males and 75 females. Skilled or semiskilled workers made up 48 per cent, domestic occupation 19 per cent, students 10 per cent, civil servants (policemen, firemen and others) 6 per cent, laborers 5 per cent. Four patients were intoxicated on admission. The majority of accidents (45 per cent) were traffic accidents, 12 per cent industrial, 12 per cent fighting or robbery, and the remainder occurred in a variety of ways. In 4 the manner of injury was unknown or complex, in 70 a fall, in 31 a blow, in 46 the patient had

been struck by a vehicle, in 38 he was a passenger in a vehicular accident, in 5 he was struck by a falling object, and only 3 were perforating or crushing injuries. Twenty patients had no period of coma, 92 were comatose or semicomatose for less than ten minutes, 42 for less than thirty minutes, 20 for thirty to sixty minutes, 17 up to six hours, 4 for six to twenty-four hours and 4 for over twenty-four hours. There was no observed disorientation in 18 patients. Disorientation was present for a period less than twelve hours in 155 patients, twelve to twenty-four hours in 4 patients, for one to seven days in 12 patients and over seven days in 11 patients. Minor abrasions or hematoma of the scalp was present in 75, laceration of the scalp in 75 and laceration with compound fracture in 6. Twenty-one patients had facial injuries in addition, 32 injuries to one or more limbs, and 8 multiple injuries. Eighteen patients had clear evidence of fracture of the skull, 16 others had bleeding from the ears or nose.

The type of head injury represented by this material is therefore representative of the admissions to most general hospitals and is predominantly that classed as "closed head injury." Few were very serious injuries, and only 3 of the whole group died during hospitalization, 1 from extensive cerebral laceration with epidural hemorrhage, 1 from laceration alone and 1 from femoral thrombosis and pulmonary embolism.

In the following analysis some terms used require definition. Coma was judged by absence of response on stimulation, the duration of disorientation recorded was that of disorientation in time, though disorientation of place and other evidence of confusion were also usually present. The durations of post-traumatic amnesia and retrograde amnesia were recorded on first or subsequent visits to the clinic at least one month after injury, when their amnesia had reached a stable minimum. Abnormalities in reflex responses in the period immediately following injury includes any sign or group of signs clearly indicating pyramidal tract disorder, whether slight or severe hemiparesis. Under the heading mental symptoms is included any complaint of nervousness, fears, anxiety, preoccupation, depression, pronounced irritability, elation, hypochondriasis or obsessional trends. Headache and dizziness were recorded separately and were not taken into account in the assessment of mental symptoms. The presence or absence of litigation, compensation or other financial, occupational and domestic difficulties was separately recorded without reference to their possible significance.

The length of follow-up was less than four months in 2 and four to six months in 48, but all these were symptom free and returned to full occupation when last seen. In 107 follow-up was for six to nine months, in 18 for nine to twelve months and over one year in 25. Disability still persisted after the last follow-up in 5 cases in which the time elapsed since injury did not allow longer than six months follow-up. In 3 cases the absence of return to work was unsatisfactory for reasons connected with the nature of employment, and in 27 cases return to full employment was impaired by other injuries or diseases unrelated to the head injury. These cases are omitted from the analytical tables relating to occupation.

NATURE OF DISABILITY

The complaints of patients convalescing from head injury are varied. They may be classified into complaints derived directly from observed structural injury

11. Pilcher, C., and Angelucci, R.: *Analysis of 373 Cases of Acute Craniocerebral Injury*, *War Med.* 2: 114-131 (Jan.) 1942.

12. Date of induction into the armed forces where this interrupted follow-up.

(symptoms of direct physical disorder), psychiatric complaints (symptoms of the order of fatigue, nervousness, anxiety, depression), symptoms of change in personality (separately coded only when there was evident aggressiveness or irritability or prolonged elation, without other mental symptoms) and complaints of uncertain or variable derivation (headache, dizziness, vertigo). In the present statistical study it was not desirable to label any group of symptoms with a clinical diagnosis, and in fact the insecurity of pathologic grounds for the commonest combination of symptoms, the "post-traumatic cerebral syndrome," was the chief reason for its prosecution. A total of 110 patients (55 per cent) complained of symptoms in convalescence (after leaving the hospital). The frequency of actual combinations of these symptoms is shown in table 1.

The complaints directly referable to structural physical disorder residual from the head injury and persisting into convalescence involved only 16 patients in the 200 under review. There was anosmia in 1 patient, paralysis of the fourth cranial nerve in 1, of the fifth in 1 (with central sensory disorder of the arm and leg), of the sixth in 1, of the sixth with bilateral seventh in 1, of the seventh alone in 1, of the seventh and eighth in 2, of the fifth, seventh and eighth in 1 and of the eighth in 1. One patient had a cerebral monoplegia. 1 had dysphasia, 1 had dysphasia and 1 convulsion. 3 developed convulsions in convalescence, and 1 of these had anosmia in addition. Seven of these patients had persistent headache in convalescence, 8 had dizziness and 12 had psychiatric symptoms.

Of the 200 patients, 81 suffered from headaches in convalescence, 63 of these for over two months. Sixty-eight patients suffered from dizziness, 46 for over two months. The most common combination was that of headache, mental symptoms and dizziness ("post-traumatic cerebral syndrome," "postconcussion syndrome"), which occurred in 15 per cent of the series of patients with head injury and in 27 per cent of those with post-traumatic symptoms. These three symptoms did not differ in any respect where they occurred alone. Headache and symptoms in the mental sphere were the commonest complaints, but there were 15 patients with mental symptoms but no headache and 28 patients with headache without psychiatric symptoms. The mental symptoms were in the form of anxiety (fears, panics) in 69 per cent of the 70 cases, fatigue, nervousness or depression in 17 per cent, hypochondria or obsessive-compulsive neurosis in 4 per cent and change in personality alone (aggressiveness or euphoria) in 10 per cent. The anxiety symptoms followed all types and severity of injury, but 6 of the 7 cases of personality change were after severe injuries with prolonged disorientation.

This report is not concerned with the mechanism of production of individual symptoms, such as headache, dizziness or mental symptoms, an analysis of which will be presented elsewhere by various members of the group. Our chief concern here is to outline the factors which were associated with disability as a whole.

SEVERITY OF INJURY IN TERMS OF ABSENCE FROM FULL OCCUPATION

In whatever way the severity of head injury may be judged, disability for employment forms a measurable standard which has a value both to the community and

to the individual. The duration of absence from work is affected by a variety of extraneous factors, among which many, such as continuance of compensation and fear of losing employment, act in contrary directions. We have not attempted to estimate such interaction in detail. Of the 200 patients 170 were absent from employment solely by reason of their head injury. Of these 42 returned within one week after injury, 71 others within one month, 23 in the second month, 20 in the third, fourth and fifth months, 9 between six and nine months, and 5 were still not fully employed after the ninth month.

In 34 patients in whom disability persisted beyond two months the nature of the symptoms which determined disability, i. e. which were alone associated with

TABLE 1.—Incidence of Symptoms, and Combinations of Symptoms, in Convalescence

Total of 110 patients with symptoms
2 had personality change only
4 had mental symptoms only
13 had headache only
8 had dizziness only
3 had physical signs only
2 had personality change plus physical signs
1 had personality change plus headache and physical signs
2 had personality change plus headache and dizziness
10 had mental symptoms plus headache
5 had mental symptoms plus dizziness
20 had mental symptoms plus headache and dizziness
3 had mental symptoms plus headache and vertigo
2 had mental symptoms plus headache, dizziness and vertigo
1 had mental symptoms plus headache, physical signs and vertigo
1 had mental symptoms plus headache, dizziness, physical signs and vertigo
4 had mental symptoms plus headache, dizziness and physical signs
2 had mental symptoms plus dizziness and physical signs
1 had mental symptoms plus dizziness and vertigo
14 had headache and dizziness only
1 had headache and vertigo only
1 had physical signs and vertigo only

disability or were blamed by the patient for his disability, were as follows:

In 20 patients anxiety symptoms (in 13 of these associated with minor headache or dizziness).

In 1 patient anxiety symptoms and dizziness.

In 3 patients anxiety symptoms with incapacitating headache and dizziness.

In 1 patient physical symptoms (7th and 8th cranial nerve paralysis).

In 2 patients dizziness alone (1 with 6th nerve palsy).

In 4 patients dizziness and headache (1 with 6th nerve palsy).

In 3 patients personality change (1 with anosmia, 1 with mild transient dysphasia).

The nature of symptoms associated with absence from full occupation lasting beyond the first month is shown in table 2. It will be noted that physical symptoms (hemiparesis, convulsions, diplopia, deafness, facial paralysis) are a relatively small cause of disability, though most are long persistent. In a group of 30 patients headache, dizziness and mental symptoms are correlated together with prolonged disability which was then directly related to these symptoms ("post-traumatic cerebral syndrome"). In many others these symptoms persisted in various combinations though full work was resumed.

RELATIONSHIP BETWEEN VARIOUS FEATURES OF THE INJURY AND DURATION OF DIS- ABILITY IN EMPLOYMENT

A large number of separate factors were separately recorded and analyzed in relation to their statistical relationship with duration of absence from full employ-

Figures in parentheses indicate patients with continuing symptoms when last interviewed. Patients whose absence from occupation was related to factors clearly unrelated to the head injury (other injuries, change of occupation) are excluded.

ment. To simplify comparison the figures are presented in tables 3 and 4 as the proportion of cases returned to full employment within two months of injury, beyond two months of injury and after six months from the time of injury. The last group is included within the second group, for some may prefer the longer period, though the smaller number of cases reduces statistical significance. The factors concerned may be grouped into general factors, for example, age, sex and race, pretraumatic factors of which the only one we are concerned with here is the pretraumatic psychiatric state, factors concerned with the nature and place of the injury, factors apparent in the clinical state immediately following injury and factors operating during convalescence.

General Factors.—Duration of disability advanced steadily but gradually in the age groups examined (table 3). A more rapid increase might be expected in the sixth decade as found in the statistics of Russell.¹ No significant effect of sex was demonstrable. The effect of higher education was of a slight and doubtfully significant increase of duration in high school or college graduates. The influence of occupation is probably related to the question of compensation as well as to age and type of injury, for civil servants (policemen, firemen and others), and laborers were relatively heavily retarded in return to occupation as compared with students or domestic workers.

Pretraumatic Psychiatric Evaluation.—The question of family history and of detailed qualities of the personality in relation to the type of mental reaction will be presented by Drs. Adler and Kozol, who conducted this psychiatric analysis. As far as the present purpose is concerned it may be noted that neurotic or psychopathic pretraumatic personalities were returned to occupation earlier than the average of those judged to be normal (table 3). Family history of psychiatric disorder was also without significance. These were unexpected findings which conflict with data derived by Symonds and Russell² from cases of war head injuries. These authors did not, however, have series of patients without symptoms for comparison. Our finding is a reflection of the very small correlation found between pretraumatic psychiatric abnormality (including minor variants) and post-traumatic mental symptoms. Of 60 patients with such post-traumatic mental symptoms 57 per cent had a positive pretraumatic psychiatric history, whereas of 123 patients who did not develop such symptoms 50 per cent had such a history. When present, however, mental symptoms had a very high correlation with disability (as shown later and in table 5).

The Nature and Place of Injury.—The place of injury was significant only in relation to traffic accidents, from which only 72 per cent of patients returned to occupation within two months, and 13 per cent were still disabled after six months. Recreational and domestic

accidents were not followed by disability lasting over two months. Disability following fighting or robbery was minimal. Industrial and street accidents other than those incurred in traffic closely resembled the average disability. The manner of injury, for example by fall or by blow, proved to be insignificant compared with the pronounced delay if it had been a fall from or impact with a vehicle. This reflects a significant relationship to the question of compensation.

The Clinical State Following Injury.—As Moore and Ruesch¹³ have remarked in a report of an earlier phase of the present study, the most accurate record of the disturbance of consciousness produced by head injury is the duration of disorientation, particularly disorientation in time. We found that the duration of coma was

only indirectly related to the total disturbance of consciousness and was more difficult to record accurately, for most patients had already commenced to make some response to stimuli when first seen, even in the admitting room. The relationship between duration of coma and duration of disability was, however, in general parallel with that of disorientation, and the scatter for post-traumatic amnesia, as might be expected, was an almost exact replica of that for disorientation. We shall therefore consider first the relationship with disorientation, shown in abridged form in table 4. It will be seen that the proportion returned to work within two months falls steadily in proportion to increased duration of immediate disturbance of consciousness. There is a significant increase in disability if disorientation is prolonged beyond twenty-four hours. The effect of durations of minutes was insignificant.

The state of confusion which precedes recovery of full consciousness may be complicated by restlessness or apathy, or in the absence of confusion emotional outbursts or restlessness may color the immediate mental picture. Any of these affective states was associated with delay in recovery compared with essentially normal balance.

Of the various direct clinical criteria of injury the presence of fracture of the skull was associated with significant delay in recovery. This delay was greater when fracture was observed on x-ray examination (58 per cent beyond two months) than when recognized by bleeding from orifices or at operation only (22 per cent). The influence of hematoma of the scalp or laceration of the scalp proved to be negligible, but laceration of the scalp with compound fracture was in a very small group associated with delay.

The presence of headache, dizziness or vomiting during hospital admission was of negligible significance. The findings in the cerebrospinal fluid (on the first or second day after injury except for 4 cases) showed no influence of increased pressure but nearly doubled the prolongation of disability if the fluid had been blood stained. There was correlation between the presence of blood in the fluid and duration of disorientation.

The presence of extensor plantar responses and increased tendon jerks with or without corresponding asymmetry of the abdominal reflexes was also associated with definite delay. Either generalized or focal activity in the electroencephalogram (table 5) was similarly associated with delay, but only in the few cases of brief focal abnormality was this delay remarkable. The confirmation of presence of subdural or epidural hematoma

earlier phase of the present study revealed only a small percentage of patients whose performance late in the hospital course (after recovery of orientation) and at the first follow-up one month after leaving the hospital had not reached a steady level. A similar small group late in convalescence failed to reach their calculated pretraumatic level based on scholastic and occupational attainment. In these groups there was slight delay in resumption of occupation. Close examination of the records of the 7 patients in the last group revealed that all except 2 had suffered trivial injury, and of them 4 had returned to work within two months and only 1 after nine months because of fears and nervousness associated with litigation. Of the 2 others, 1 had been disoriented for five days and had slowness in thinking for some nine months but had returned to full work within two months. This patient was completely recovered in one year. The remaining patient had been disoriented for twenty-four hours and was mentally slowed for ten weeks but then had recovered completely and returned to work. All 7 patients were under the age of 24 years. Persistent intellectual defect residual from prolonged disorientation therefore cannot appear as a factor in disability as a whole and was clearly operative in only 2 patients (1 per cent).

Hematoma, subdural *.....	9	33	67	22

* Separate series of hematomas of wider age range from the whole group of 430 cases for comparison.

Factors Operating in Convalescence.—The presence of complications in convalescence, including litigation, compensation or insurance, domestic and family troubles, occupational difficulties, other financial problems, other diseases or injuries or more than one of these was carefully recorded, regardless of the opinion of the significance of each. Questions of compensation, occupational difficulties and the presence of other diseases or injuries (though the head injury was blamed by the patient) emerge as of high significance, as also did combinations of factors (usually involving compensation). Domestic difficulties and financial problems other than compensation proved to be without statistical effect.

The symptoms present in convalescence have been examined in their relation to disability in the preceding section. It may be noted that mental symptoms of any kind had an extremely high correlation with disability. Of patients with such symptoms only 53 per cent were back to full occupation within two months and only 76 per cent within six months. Of patients without such symptoms, 95 per cent returned to occupation within two months and 100 per cent within six months. Headache had less correlation with disability than had mental symptoms (tables 2 and 5).

Relationship Between Initial Surgical Diagnosis and Disability.—It is also of interest to compare the prog-

nosis with regard to employment disability in the various diagnostic categories in closed head injury (Munro¹⁰). If by concussion is understood an immediate disorder of consciousness without change in the spinal fluid or other evidence of structural damage to the brain, by edema is meant the same clinical phenomena but with raised pressure in the cerebrospinal fluid (over 200 mm.), and by cerebral laceration the finding of blood in the spinal fluid with or without loss of consciousness, and without paralysis or change in reflexes; the figures for these conditions as they occurred in the 200 cases are given in table 6. The presence of disorder of consciousness with abnormal neurologic signs—hemiparesis, facial or other weakness or cranial nerve injury—is listed as a further, separate category. A small series of acute subdural hematomas is included for comparison.

Whereas such diagnostic categories had little value in prognosis as between concussion, edema and laceration, the prognostic value of separation of all cases showing abnormal neurologic signs, whether of reflexes, of central paralysis or of cranial nerve palsy, is emphasized. This, however, is only one aspect of the subject, for it will be noted that disability lasting over six months was as common after trivial injuries as of those with neurologic disorder. Only when the environmental factors of the injury are taken into consideration is this discrepancy accounted for.

The Post-Traumatic Cerebral Syndrome.—The 30 patients who suffered from the combination mental symptoms plus headaches plus dizziness were of particular interest in view of the literature that has accumulated around this "postconcussion syndrome." The age and sex distribution did not differ from that of the whole group. All had lost consciousness except 3, but only 13 had disorientation for over one hour, and only 3 for over twelve hours. Laceration of the scalp had occurred in 19, and only 4 had no outward sign of head injury, neurologic signs were positive in only 2, and the spinal fluid was blood stained in only 5 (not examined in 5). Electroencephalographic abnormality occurred in 8 (not examined in 8). In terms of the foregoing classification 20 of these patients had suffered from concussion. In the whole group the headache was decidedly influenced by posture in 8 and by effort in 12. The dizziness was directly influenced by change of position in 21. There was a history of pretraumatic neurosis in 6, of personality disorder in 8. Litigation complicated convalescence in 18, occupational difficulties in 11, and only 2 lacked any complication in this period. There was return to full occupation in less than two months from injury in 14, in more than two months in 13 and only after six months in 7 of these (table 5). In 3 working efficiency was disturbed by other causes.

The "post-traumatic" or "postconcussion" syndrome was therefore commonest following minor injury, and the frequency of scalp injury and of complicating environmental factors in convalescence are notable. Even in the very high correlation of these features the full syndrome only slightly exceeded the correlations of any of the symptoms occurring singly or in other combination with the same factors. In terms of disability from employment the postconcussion syndrome has the same prognosis as have the mental symptoms of which it is partly composed (table 5).

The Outcome of Prolonged Disorientation.—Mental symptoms followed severe injury (disorientation over twenty-four hours) in 15 of 23 patients. In 2 of these

the symptoms were of fatigue and nervousness, in 7 of anxiety and in 6 of personality change alone. Of the latter 3 were delayed beyond two months in return to occupation and in 2 of these cranial nerve paralysis and epilepsy were given as the cause of delay. Anxiety and related states remained highly correlated with disability in the group, all 9 being greatly delayed in return to occupation. The group of severe injuries without mental symptoms all returned to occupation within two months or were delayed by other injuries. The features of severity of injury which indicate a bad prognosis were therefore resolved into great likelihood of cranial nerve injury, epilepsy or associated injury to parts other than the head, and also an increased liability to anxiety symptoms. The proportion of headache and dizziness remained the same. We therefore submit that the term "postconcussion syndrome" be dropped.

SUMMARY

Statistical analysis of the association of various features of the head injury with the resulting absence from employment indicate a constellation of features which correlated with prolonged convalescence. The relative degrees to which prognosis was thus affected may be indicated in the list presented in table 7, in which factors are represented in order of percentage disability.

From our whole analysis it appears possible to reach a generalization that the factors of prognostic ill omen can be arranged in two chief groups, those that are indicative of injury to the brain and those which relate to the environment. In the former, focal neurologic signs, focal or general electroencephalographic change and prolonged disorientation appear to be of primary pathologic significance, and the presence of blood in the spinal fluid and fracture of the skull to be less directly associated. In the environmental group are sources of anxiety derived from the injury, the initial emotional disturbance, the circumstances of employment or place of injury which predicate problems of compensation, and the circumstances and duration of convalescence, which breed anxiety as to personal or family security.

In some hospitals, particularly those serving centers of heavy industry, a greater proportion of compound fractures of the skull might be expected, with corresponding increase in disability. The type of head injury here represented, however, is held to be fairly representative of average accident admissions.

Headache was the most frequent symptom following head injury, and the combination of headache and dizziness undoubtedly causes much distress. These symptoms had, however, a relatively small association with disability from occupation. Without prejudice to their essential nature, their value in causing disability was found in their association with mental symptoms.

The insignificant part played by defect in intellectual function requires special comment. The performance tests used showed well defined defects only in the hospital course with subsequent improvement and were selected from two preliminary batteries devised to emphasize the type of performance defect (Ruesch and Moore¹⁴). In addition a standard intelligence test (Wechsler-Bellevue) was administered by Dr. Cole in follow-up. Defective performance persisting for long periods was demonstrated in some patients (Ruesch¹⁵), particularly following prolonged post-traumatic confusion (Moore and Ruesch¹³). The elimination of patients over 55 years of age and of chronic alcoholic addicts from the present analysis, however, elimi-

nated all such examples of "post-traumatic dementia" (Denny-Brown,¹⁶ Cole¹⁷). Persistent mental slowing was seen in 2 patients with ultimate recovery but did not account for prolonged disability. It is possible that severe cerebral lacerations by penetrating injuries would leave more persistent intellectual impairment, but the best examples in our series, one of whom had extensive laceration of both frontal lobes by a buzz saw, made a remarkable recovery in all performance tests. The conclusion further throws doubt on the ability of trauma alone to induce persistent dementia in a healthy brain.

Head injuries with prolonged disturbance of consciousness, blood in the spinal fluid and positive neurologic signs following the injury led to transitory intellectual slowing, persistent headache and dizziness, disorder of personality, cranial nerve paralysis, epilepsy or combinations of these. All these after-effects account for only a small part of prolonged disability (29 per cent of 34 cases). In the remainder the patient attributed his disability to symptoms clearly referable to an anxiety state (anxiety neurosis) even after the

TABLE 7.—Factors of Bad Prognostic Significance

In Relation to Return	
Within Two Months	Within Six Months
Disorientation over 7 days	Disorientation 1-7 days
Disorientation 1-7 days	Laceration of scalp with compound fracture
Transient abnormality in electroencephalogram	Initial apathy
Initial restlessness or excitement	Age over 40 years
Abnormality in reflexes	Injury to other parts
Other disease or injury complicating convalescence	Disorientation over 7 days
Questions of compensation or litigation	Blood in cerebrospinal fluid in first 2 days
Fracture of the skull	Fracture of skull
Blood in cerebrospinal fluid in first 2 days	Abnormality in reflexes
Initial apathy	Initial emotional disturbance
Defect in intellectual performance late in hospital stay	Other disease or injury complicating convalescence
Age over 40 years	Electroencephalographic abnormality
	Questions of compensation or litigation

most severe injuries. If a judgment were allowable in relation to certain cases of isolated headache or dizziness the proportion would be higher. We therefore find no reason to separate the after-effects of injuries with transient disturbance of consciousness from those of more severe injuries, except that the latter contained a larger proportion of residual physical symptomatology. The predominating association with occupational disability in all types of head injury was anxiety state (anxiety neurosis).

The effect of head injury on the individual involves a complex readjustment in which a large number of different factors are reflected. In the absence of influence of age, which the selection of material in the study has tended to minimize but which began to be apparent as early as the fifth decade, the psychiatric structure existing before the injury was found to have a surprising absence of effect on the end result. The circumstances of the injury, the duration of disturbance of consciousness and the environmental factors in convalescence were the factors of greatest importance. Of the latter occupational difficulties were as important as

16. Denny-Brown, D.: Intellectual Impairment and Head Injury, *A. Research Nerv. & Ment. Dis., Proc.*, to be published.

17. Cole, E. M.: Intellectual Impairment and Head Injury, *A. Research Nerv. & Ment. Dis., Proc.*, to be published.

questions of compensation. Therapeusis directed to lessening post-traumatic disability would appear to have greatest promise in the direction of psychiatric control of the effect of these factors, by which is meant an attempt to minimize their potency in the production of persistent symptoms of anxiety. Finally, this study indicates that the high percentage of anxiety symptoms reported to follow the head injuries of war is not peculiar to that circumstance.

CONCLUSIONS

1. Out of 430 consecutive admissions to the Boston City Hospital immediately following head injury a series of 200 cases, selected only by exclusion of age groups under 15 years and over 55 years, and of vagrants and chronic alcoholic addicts, was followed for intervals of six months or longer. Each patient was examined soon after admission and at regular intervals thereafter by a team consisting of neurologists, psychiatrists, a psychometrist, an electroencephalographer and a social worker.

2. The majority of injuries (53 per cent) were derived from traffic accidents, and relatively few were of great severity, consisting chiefly of "closed head injury" with varying degrees of scalp injury and loss of consciousness. Twenty-seven patients had post-traumatic amnesia lasting over twelve hours, 22 patients over two days, 8 over seven days. Eighteen patients had clear evidence of fracture of the skull.

3. One hundred and ten patients (55 per cent) complained of symptoms in convalescence. The symptoms were related to structural physical disorder in 16 patients, to psychiatric symptoms in 70, to headaches in 81 and to dizziness in 68. These symptoms were frequently associated, but each could occur alone. The association of headache, dizziness and psychiatric symptoms ("postconcussion syndrome") occurred in 30 patients.

4. Absence from full occupation occurred in 30 cases by reason of other injuries or unrelated causes. In the remaining 170 patients, 136 returned to full occupation within two months, 16 in the third and fourth months, 4 in the fifth and sixth, 9 between six and 9 months, and 5 nine months or more after injury. Such disability has variable relationship to the various post-traumatic symptoms. Psychiatric symptoms had the highest correlation with prolonged disability.

5. Factors of bad prognostic significance in relation to return to occupation within two months of the injury, and within six months of the injury, were analyzed. In each case features indicative of severity of injury (prolonged disorientation, abnormal neurologic signs, blood in the spinal fluid, electroencephalographic abnormality) and those indicative of psychologic stress (initial excitement or apathy, occupational worries, anxiety over compensation) were intermingled.

6. The symptoms associated with prolonged disability, whether the injury had been severe or mild, were predominantly mental symptoms related to anxiety. Even after severe injuries cranial nerve paralysis, dizziness and headache, and personality change accounted for a minor part of disability. Intellectual disorder played no significant part.

7. The environmental factors of the injury were in total effect more important in accounting for disability than were the factors indicative of severity of injury, but neither can be neglected in the assessment of prognosis. The extensive association between head injury and psychiatric factors indicates possibilities for lessening disability by psychiatric treatment.

STIFF NECK AND MENINGEAL IRRITATION

JOHN A. TOOMEY, M.D.

CLEVELAND

Stiffness of the neck is often found in clinical practice accompanying meningeal irritation. Yet, paradoxically enough, patients have been erroneously diagnosed as having had meningitis because of its presence. We had to note the conditions where stiff neck was found, for it soon became obvious that not all stiff necks were due to meningeal irritation.

In order to establish a diagnosis when this condition is present, one has to collect the evidence based on inspection, percussion, palpation and rarely auscultation. The factors causing stiffness of the neck originate in nerves, muscles, bones, fascia, ligaments, glands and other structures. The neck is inspected from front, side and back. One notes how the head is held. Is it braced and splinted to avoid pain? Is there pain in certain positions only? Is pain absent? Is the entire head and neck moved in a marionette manner or is the neck stiffened so that forward movement is impossible while lateral movement is still tolerated? The neck should be palpated along the posterior spine for bony landmarks, along the occiput and mastoid portions of the temporal bones, over the paranasal sinuses, at the base of the sternocleidomastoid muscle insertions, along the course of this muscle, and in all the triangles and fossae of the neck. Is any bone more prominent or more tender than usual? Is there a cervical rib or scalenus anticus syndrome? Are there tumors present fixing the surrounding tissue? Is it possible to overcome the stiffness or muscle spasm present by continuous gentle forward pressure? The finger should be inserted into the pharynx and its walls palpated, especially in the lateral direction. Auscultation gives information only occasionally, such as when air is present subcutaneously or a bruit may be heard over the thyroid. The latter are facts of academic interest and of little importance in the present instance.

Any organism can cause meningitis with evidence of meningeal irritation, including a stiff neck. The stiffness is always found present except under three circumstances: (1) when there is extreme toxicity and death occurs a few hours after the infection has started, i. e. with a fulminating infection, (2) sometimes if the patient has been sick a long time and is examined just before death and (3) when the patient is an infant.

The stiffness present in meningitis is against forward motion of the head; lateral movement is usually possible. It is accompanied by other findings—a positive Kernig reaction, perhaps a Brudzinski sign, opisthotonos and pain along the back. The mere presence of stiffness and a positive Kernig reaction indicates a meningeal irritation.

It has become a habit with clinicians to attempt to raise the head forward from the supine position and if there is pain or resistance to conclude that the patient has meningitis. This does not always follow. This resistance to head flexion is sometimes referred to as

From the Department of Pediatrics, Western Reserve University Department of Contagious Diseases, Cleveland City Hospital.
Read before the Section on Miscellaneous Topics, Sessions for the General Practitioner, at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

a Kernig sign. This is incorrect. The examiner must flex the thigh on the abdomen and attempt to straighten out the leg at right angles to the body to demonstrate the original Kernig maneuver. The patient ill with meningitis will not only have resistance when the head is lifted and bent forward but he will also have a positive Kernig reaction (Brudzinski's sign). When the neck of a patient with meningitis is pulled forward, the legs may flex themselves simultaneously. This is similar to the Brudzinski contralateral reaction in the other leg when the Kernig maneuver is done. The important point is that, no matter how stiff the neck, the Kernig sign in the legs must also be positive or the patient does not have meningitis. The one exception is a meningeal irritation, which occasionally accompanies a lower motor neuron disease like poliomyelitis.

The reverse opinion is sometimes held that there can be no meningitis if the neck is not held in a well stiffened position. In the main this is true of those infections of the meninges due to pyogenic organisms. However, the patient may, as stated previously, lose this response just before death if he has overwhelming toxemia or if he is an infant less than a year old. In the latter instance the other signs are sudden onset, high fever, a bulging fontanel and perhaps convulsions.

Stiffness with meningitis persists until the patient is better, usually for two or more weeks or if the disease is fatal until just before death, when all reflexes may disappear. It is important, therefore, to stress the "persistence" of meningeal signs. A patient may have a stiff neck accompanied by meningeal signs and yet not have meningitis. This happens in three conditions, namely pyelitis, infectious diseases of the gastrointestinal tract and pneumonia. If the patient is a female with a spiking type of a temperature curve who has signs of meningitis that do not persist but come and go, the diagnosis is usually pyelitis. One of the stiffest necks I have seen was present in an 11 year old boy with pyelonephrosis.

There may be localized spots of irritation in the neck, Capps points, which when present indicate a diaphragmatic pleurisy. If the patient has referred pain in the so-called deMuzzy's buttons, one an inch out and a half inch up from the umbilicus, one underneath the ninth rib at the juncture of the lateral rectus line, one in the back along the spine in the region of the sixth vertebra, there may be phrenic irritation with an early pneumonia. If in addition to the foregoing the abdomen is splinted and boardlike and associated with pain on pressure over the lower ribs, the diagnosis usually is pleurisy and early pneumonia, and the stiff neck can be ignored.

A stiff neck is frequently found in patients with severe typhoid, fleetingly with paratyphoid A or B infections of the intestine.

Only one type of meningeal irritation gives a bizarre reaction. Here, as the clinical course progresses, the neurologic signs become bizarre in character and actually different on one side as compared to the other, on the same and on different days, with a varying of spasticity and flaccidity. The eyes are out of focus. Such a picture is practically always indicative of a tuberculous meningitis. In this condition all the signs of meningeal irritation may at times be completely absent.

Stiffness is present with acute infections of the central nervous system other than those causing a leukocytic

reaction. It is a common finding with virus infections. In poliomyelitis the stiffness or flexor muscle spasm lasts for a few days only—twenty-one at the most. If the muscles of the leg are not involved, a classic Kernig response can be obtained. If they are paralyzed, the mechanism for its production is lost.

Should the neck be stiff and should there be signs of a lower motor lesion, i. e. decreased or absent reflexes and nuclear paresis or paralysis, the chances are that the patient has a lower motor neuron lesion with meningeal irritation, probably poliomyelitis. On the other hand, if signs of meningeal irritation, including a stiff neck, are present together with signs of an upper motor neuron lesion, i. e., positive Babinski, Oppenheim, Gordon or other reflexes, hyperactive, deep spinal reflexes and spastic muscles, the patient has an upper motor lesion with meningeal irritation.

A stiff neck caused by exposure to wind or cold is seen in the winter time. Movement of the neck becomes very painful.

Sudden changes of temperature, air conditioning and so on have a profound effect on some persons. The neck stiffens and there will be a low grade pain, almost like a dull toothache. The history helps here. The true Kernig sign will be negative. The neck can be moved through all its arcs of motion by constant but gentle pressure—movements not possible for the patient with meningitis. This condition can be relieved by hydrotherapy.

Lymphatic glands may be found in and about the sternocleidomastoid muscle on all sides. A focus of infection in the mouth, tonsils or throat drains to the local lymph glands. These may swell to the point where they irritate the surrounding tissues and cause the production of spastic muscles and a stiff neck. Movement may become so painful that the head will be voluntarily held splinted. The patient moves with robot-like stiffness, and the entire back is used as a pivot when turning. Gentle persistent pressure, even though painful, will allow the operator to move the head in all directions. Finding a focus and localizing the swelling to the lymph glands by palpation rule out meningeal irritation. The convincing evidence is that the neck can be moved forward with persistent pressure.

A common cause of stiff neck is neuritis, often of the occipital nerve. These patients are sometimes diagnosed as having meningitis. When examined, it will be found that, although the neck is mobilized and held stiff, it also can be moved if pressure is applied slowly. The pain is present all the time, whether the neck is moved or not. Heat may relieve the pain. Trigger areas are found in the back of the neck and head, which when pressed cause sharp pain. Often if the pressure is slowly and continuously applied over those points the pain disappears. The pain is constant and may be like that with a unilateral migraine headache. The vessels of the painful side may be dilated during attacks. If these are compressed, the pain may disappear. The lack of fever and the past history of previous attacks help rule out any meningeal irritation.

Occasionally swellings will begin in the floor of the mouth and extend laterally in and along the subcutaneous tissues of the neck, fixing it with boardlike rigidity. Ludwig's angina is easy to differentiate, since there is brawny induration of the anterior portion of the neck and floor of the mouth. "Bull neck," which

fixes the head likewise and occurs in diphtheria, may be preceded by glandular enlargement followed later by a sudden swelling of the subcutaneous tissue. Often, however the swelling may come on suddenly without previous glandular enlargement and the whole area of the head and neck becomes fixed. There should be no difficulty in differentiation here.

A Bezold's abscess may irritate the sternocleidomastoid muscle at its insertion and cause a spasm which fixes the neck. Here the history of an acute otitis media, probably purulent in type, pain over the mastoid and the like should give the clue. Likewise the swellings which fix the position of the head may start about the face in the preauricular lymph glands, in the parotid and in the buccal lymph gland. The location of the swelling is the differential point in the diagnosis.

Osteomyelitis of the skull bone or of the vertebrae causes fixation of the neck. Tuberculosis of the cervical spine is a frequent cause of stiff neck. The head is splinted; the merest movement causes great pain, which is usually localized. The patient holds the head in his hands when turning from side to side, so that there will not be the slightest jar—quite unlike the patient with meningitis, in which lateral movements are not usually accompanied by pain. The history completes the picture. It is much more difficult to differentiate meningitis from tuberculosis of the lumbar vertebrae; in fact, toward the end of the clinical course, even in tuberculosis of the lumbar area, there may also be an associated meningitis. Where there is no associated meningitis, splinting will be found in all the muscles of the lumbar area and not in the neck region.

A few patients with dislocation of the cervical bones have been admitted to our service diagnosed as having meningitis. The position of the patient and the fact that there is no true Kernig sign should put the physician on guard. One can easily palpate the dislocation through the pharyngeal wall, and the x-ray examination will confirm the diagnosis.

Patients with retropharyngeal abscesses may be diagnosed as having meningitis because of the peculiar posterior bowed position of the neck. If one watches such an individual, two things are observed as peculiar and hence typical: the type of breathing and the position of the patient. The child's inspiration and expiration are harsh and rasping, but cyanosis, anoxemia and air hunger are not present, provided he is inactive and does not have to breathe too fast. The child always assumes the "bronchoscopic" position, i. e. head forward and tilted back, the chin up, the rest of the body bowed back. He lies on his side, never on the back. The palpating finger makes the diagnosis definite. X-ray examination confirms it. Most of these abscesses are lateral to the midline and cannot be seen on inspection.

Children and adults often sleep in cramped positions and awaken in the morning with stiff necks. There is no fever. There is only pain on movement and, paradoxically, in the average patient the more movement is employed the less the pain seems to become until finally the muscles may be worked loose entirely. In any event the neck can be moved about.

A patient with congenital wry neck (*torticollis*) presents no diagnostic difficulties. The scar tissue present may cause fixation of the neck by its contraction. Unilateral spasmodic wry neck is easily recognized, since the head is pulled and held to one side with intense

pain. The child with a bilateral spasmodic wry neck may confuse one for the moment, but palpation and history will soon rule out meningitis.

Older persons with arthritis are occasionally admitted as having meningitis. Most of us have some arthritis after a certain age, an arthritis which may progress to the point of ankylosis without pain, although with limitation of movements and then out of a clear sky pain and muscle spasm will occur. Here the history helps. In the deforming type of reaction, spondylitis deformans, the poker back and the ankylosed vertebrae are obvious. They are easily palpated, and the contour of the spine is revealing.

Injury, twists of ligaments and fractured vertebral processes or body sometimes cause stiffness. A sudden jerk of the head or twist of the body may pull a ligament away from the ends of a transverse process. Such a patient often complains of more pain than does one with a more serious impacted vertebral fracture. A few such persons have been admitted because of stiff neck and back, but the lack of any neurologic findings and any signs of a febrile reaction has prevented us from laying too much stress on the stiff neck present.

Tetanus as well as rabies may cause a stiff neck during the course of spasms. In tetanus or any other condition treated intraspinally with horse serum, a sterile meningitis may develop with a stiff neck which will not disappear for a few weeks.

All of the types of encephalitides may cause a stiff neck. If a meningeal reaction is present there is usually a pronounced increase in the amount of albumin present in the spinal fluid and in the number of cell forms. If the cellular reaction is slight and the albumin present scant in amount, there is little meningeal irritation and but little stiffness of the neck.

In the usual type of sleeping sickness with but few cells present in the spinal fluid, the stiffness of the neck may be only occasionally present. However, it is often seen with other forms of encephalitis, such as the Japanese type B, St. Louis, lymphocytic choriomeningitis and equine encephalomyelitis.

The apoplectic individual with massive hemorrhage is usually in shock and exhibits no stiffness until perhaps a week or two has passed and sometimes not even then. The individual with a slow meningeal bleeder, one with a ruptured berry aneurysm or a ruptured basilar vessel, if not killed by the condition within a short time after the break occurs, may have nothing besides headache and an extremely stiff neck. The stiffness becomes more pronounced if bleeding persists. Other signs help differentiate, such as signs of increased intracerebral pressure and gradual onset of unconsciousness. The lumbar puncture helps to make the diagnosis definite.

Other conditions have at times produced a reaction in the neck, including brain tumors with increased intracranial pressure, fractures of the skull with extravasation of blood, pachymeningitis, mastoiditis, zygomatic mastoiditis, ethmoiditis, lead poisoning, uremia and toxic neuronitis.

Enough has been said to indicate that a stiff neck may not always mean that the meninges are irritated; nor does the absence of a stiff neck always rule out a meningitis. It is a sign which, if present without other signs of meningeal irritation, may usually be ignored.

3395 Scranton Road.

ABSTRACT OF DISCUSSION

DR. GILBERT J. LEVY, Memphis, Tenn.: One of the most frequent and common causes of stiff neck seen in children by both general practitioners and pediatricians is acute lymphadenitis of the neck. This focus of infection may originate in the sinuses, mouth, tonsils or throat. In this clinical condition the painful neck movements and voluntary head splinting are characteristic. Dr. Toomey has described how these glands swell and irritate the surrounding tissues with the resultant spasticity and stiffness of the muscles. Not infrequently you will be rewarded by finding on deep palpation that these glands have extended as far down as the clavicle on one or both sides of the neck. The symptoms of stiff neck in infants at times present a most baffling problem. Nuchal rigidity may or may not be present. The young infant lies motionless and has a shrill cry. Attempted flexion of the neck offers little information. Frequently acute gastrointestinal infections, pyelitis, pneumonia and occasionally malaria may be the answer. One manifestation of stiff neck and meningeal irritation, which is on the increase, certainly in our section of the country, is lymphocytic choriomeningitis. One striking feature of this clinical condition is the pronounced rigidity of the neck, though most of these patients do not appear unusually ill. Tetanus, a decreasing disease, illustrates clinically stiff neck more than any other disease. I believe that most physicians will agree that in tetanus the head is "heavier," because of the increased muscle spasm, than in any other clinical entity. Rabies likewise may or may not produce stiffness of the neck. At the isolation hospital we have encountered 3 cases of pseudolyssa, or hysteria, which were admitted as cases of hydrophobia. Two gave a history of dog bite and 1 of cat bite. A quick and ready appraisal to the diagnosis which has never been found wanting is to stand quietly behind the patient at the head of the bed and exert sudden but firm pressure under both supraorbital ridges. The results are understandable.

DR. ARCHIBALD L. HOYNE, Chicago: The significance of stiff neck may be trivial or it may be of the utmost importance. Not every patient with a stiff neck has meningitis, nor does every meningitis patient have a stiff neck. We have had fatal cases of whooping cough where autopsies disclosed that infants died of extensive pneumococcal meningitis, a condition not considered during the life of the patients. An acute infection may cause stiffness of the neck. Prior to the days when typhoid was a rarity in Chicago it was frequently confused with meningitis. In the present season, with the likelihood of poliomyelitis appearing, probably every child with a stiff neck will be suspected of having either poliomyelitis or meningitis. While there is nearly always stiffness of the neck in poliomyelitis, usually the patient also has at the same time a head drop which is not commonly seen with meningitis. It was gratifying to hear Dr. Toomey state that intraspinal treatment causes stiffness of the neck. Some years before the introduction of the sulfonamide drugs, we abandoned all intrathecal therapy. Nevertheless most of us can look back and recall that a good many patients recovered, in spite of the old methods of treatment. One of the questions to decide is whether stiffness of the neck is voluntary or not. Patients who are sent to our contagious disease hospitals in Chicago with a diagnosis of meningitis always receive a lumbar puncture, even though we may believe that meningitis is not present. Therefore patients who are thought not to have meningitis are more certain to have a spinal tap than patients for whom we think the diagnosis is assured. If the diagnosis is verified either by a blood culture or possibly by a smear from petechiae in the skin, usually a lumbar puncture is necessary. The paper of Dr. Toomey's is of immense importance. He has covered far more completely than most people could all of the various circumstances which may contribute to a stiff neck. Outside of a hospital few physicians would be likely to witness all of the conditions which Dr. Toomey has referred to and described so clearly.

DR. JOHN A. TOOMEY, Cleveland: When Dr. Hoyne mentioned the war I thought he was about to call my attention to the fact that concussion can cause stiff neck. He referred to whooping cough. This reminded me that I had forgotten

to mention whooping cough encephalitis, although it could be inferred, since I stated that any acute infection may be the cause of a stiff neck. A spastic hemiplegic condition may develop during the course of whooping cough, a condition from which recovery usually occurs. If it does not there is flexion contraction of the fingers with an atrophy of the face on the ipsilateral side. Dr. Hoyne stated that intraspinal injections could cause a stiff neck. Penicillin should be mentioned in this connection. One wonders why in the treatment of meningitis (epidemic) patients should be subjected to daily injections of penicillin for two or three weeks when they can be benefited and almost cured within forty-eight hours by the use of meningococcus antitoxin and sulfonamide drugs. Sometimes a most severe stiff neck will accompany early rheumatic fever.

OVERTREATMENT DERMATITIS

L. EDWARD GAUL, M.D.

DUBUQUE, IOWA

Almost every day skin lesions are observed that have been made worse by imprudent topical therapy. Even neoplasms are not spared from the "put something on it" impulse. A similar situation must exist on the West Coast, because at a forum on Overtreatment in Dermatology Miller¹ stated that "a comparatively large number of patients in routine dermatologic practice are forced to seek treatment because of irritation from remedies applied and not due to their primary complaints." Apparently all that the skin has to do is to complain a little—an evanescent erythema or pruritus—and it is impulsively daubed with the nearest thing at hand. This practice often causes needless complications, loss of gainful work, unnecessary expense and hospitalization, even the acquiring of cutaneous sensitization.

PLAN OF STUDY

While the routine dermatologic history was being taken the previous treatment was recorded in sequence. A duplicate list of these preparations was given the patient. This procedure made the collection of remedies used as complete as possible. During the interim and depending on the indications, saline compresses were advised or a colloidal clay lotion or paste. Usually the patients returned the same or the following day with the remedies. Patch tests were performed with these as well as with other suspected contactants and read in forty-eight hours.

Three criteria were set up to guide this study:

1. The patch test had to reproduce in miniature some of the characteristics of the presenting dermatitis.
2. The patch test reaction had to persist at least four days.
3. When the irritant present in a remedy was removed, the superimposed dermatitis had to involute in a reasonable time, about three weeks. When these criteria were satisfied it was concluded that the initial skin lesion had been complicated, made worse, by remedies applied.

REPORT OF CASES

The following reports were selected from the series² observed to illustrate the most common classes of skin lesions the recipients of overtreatment. The success

1. Miller, H. E.; Ayres, S. Jr., and Alderson, H. E.: *Overtreatment in Dermatology*, California & West. Med. 51: 251-253, 1939.
2. Organic mercury compounds have led all the other cutaneous drugs in producing positive patch tests. It would seem appropriate that tinctures, salves and lotions containing a mercury compound should bear a warning on the label of the presence of a sensitizer.

achieved by "taking something off" stands out in sharp contrast to the complications produced by the common tendency of always "putting something on."

CLASS 1.—Physical agents causing superficial injury—actinic, thermal or traumatic:

CASE 1.—S. M., a white woman aged 20, a student nurse, was referred for a dermatitis of the left hand.

History.—Three weeks previously the dorsum of the hand was burned from spattering bacon grease. Several pea size blebs appeared, which were opened and painted with the tincture of an organic mercurial. The following day the lesions were swollen and inflamed. During the ensuing three weeks petrolatum gauze, sulfanilamide and sulfathiazole powders and ointments, boric acid ointment, a burn ointment and calamine lotion were applied.

Examination.—The dorsal area of the left hand was occupied by a tense bullous lesion. The central portion was hemorrhagic.

Course.—Saline compresses were applied with instructions to change every four hours. The following day a generalized morbilliform eruption appeared and the patient was hospitalized. The buccal mucosa was eroded opposite the lower left first molar tooth. The latter had been filled with amalgam one year before. Within four days the hand showed definite improvement and simultaneously the body eruption faded. Also the erosion in the mouth disappeared. At the end of a week the patient left the hospital. The saline compresses were discontinued after six days and a colloidal clay lotion was substituted. The lotion was withdrawn within a week as the result of rapid involution. The periphery of the lesion showed coalescent pea sized areas of depigmentation.

Laboratory Tests.—The routine examinations were negative. When the dermatitis had cleared, patch tests were performed with the remedies. The tincture of the organic mercurial induced only an erythema. The burn ointment was 4 plus, producing a miniature bullous lesion. The manufacturer supplied the ingredients and all patch tests were negative except the organic mercurial, which was applied in an aqueous dilution of 1:100,000. This dilution produced a bullous lesion. Again the tincture induced a simple erythema. The patch test with the aqueous organic mercurial produced a flare of erythema about the site, and simultaneously the erosion appeared on the buccal mucosa opposite the amalgam filled tooth. There was no reaction opposite the older amalgam filled teeth.

Progress.—All was well with this patient for six weeks, when suddenly a bullous dermatitis appeared on the palmar and medial surfaces of the middle and ring fingers of the left hand. Some thermometers had been removed from a solution of mercury bichloride 1:100. The patient had been warned of a mercury sensitivity. Two weeks later a patch test with mercury bichloride 1:100,000 produced a bullous lesion at the site. Again the erosion appeared in the mouth. The areas of depigmentation on the hand have persisted for four months.

Comment.—Several superficial burns caused a total disability of the left hand for two months and a week of hospitalization. Three consultants advised a change of education so as to avoid mercury contact. The acquired mercury sensitivity dates from this episode.

CASE 2.—R. A., a white boy aged 13, a farm boy, was referred for a dermatitis of the right elbow, knee and forehead.

History.—Two weeks previously the patient fell off a pony and scratched the skin of the knee and elbow. The areas were wiped with kerosene and a burn ointment was applied, followed by a pink salve, boric acid ointment and a white salve. A week later a dermatitis appeared on the forehead limited by the sweat band of a straw hat. The same hat had been worn the two previous seasons.

Examination.—The forehead showed two rectangular areas of dermatitis. The right knee and elbow region showed a weeping and crusted inflammation.

Course.—Saline compresses were applied for four days, changed three times daily. A colloidal clay paste was then

applied for one week. The area of dermatitis on the forehead cleared in ten days, that on the elbow and knee in less than three weeks.

Laboratory Tests.—Routine examinations were negative. All patch tests were negative except the leather hat band and the burn ointment. The label of the latter declared thirteen different chemicals, including an organic mercurial. The ingredients have been requested but as yet they have not been received.

Comment.—After the dermatitis involving the extremities had cleared, the straw hat was worn without causing trouble. A later patch test to the sweat band was negative. This episode caused a partial disability of five weeks.

CLASS 2.—Dermatitis—atopic or contact:

CASE 1.—S. G., a white woman aged 30, a housewife, was seen for a generalized dermatitis.

History.—Since puberty the patient had had recurrent attacks of dermatitis involving the atopic areas each spring. Four days previously she applied a salve recommended by a friend. The following day the areas of existing dermatitis became acutely inflamed.

Examination.—The flexor surfaces of the extremities, the neck, the chest and the abdomen showed a diffuse, brightly erythematous dermatitis. It outlined the sweep of the hand over the involved areas.

Course.—A cleansing bath was advised followed by a tepid bath to which had been added 2 cups of oatmeal. A colloidal paste containing 5 per cent olive oil was used twice daily thereafter. The dermatitis cleared in less than ten days.

Laboratory.—Routine examinations were negative. A patch test with the ointment was 4 plus. The site showed a brilliant erythema. The ointment was a refill prescription and it was impossible to learn its composition.

CASE 2.—B. E., a white man aged 48, a mailman, was referred for a dermatitis of the right forearm, thigh and abdomen.

History.—Two weeks previously while painting his house the patient noted one evening several streaked blebs on the right forearm. The following day a poison oak lotion was obtained and applied. Several days later the arm began to swell and the skin became covered with blisters. Three daily injections of a preparation for poison oak were given and then the lesions on the abdomen and thigh appeared. For the last four days a white salve had been used.

Examination.—The right arm showed a tremendous edema and inflammation. The bony markings were obliterated. The skin was a mass of discrete and coalescent vesicles which brought to mind the appearance of a cobbled stone street. The lower right quadrant of the abdomen was covered by a giant urticarial wheal, and a lesion of about the same size involved the lateral midportion of the thigh.

Course.—The right arm was elevated and saline compresses were applied. They were changed four times daily. Within four days the edema had lessened and many of the vesicles had ruptured or exfoliated. A colloidal clay lotion was applied for one week. By this time the dermatitis was rapidly clearing.

Laboratory Tests.—Routine examinations were negative. All patch tests were negative except the poison oak lotion. A cluster of vesicles were visible at the test site. The manufacturer supplied the ingredients, and the irritant was grindelia. The patch tests with each remained for nine days.

Comment.—This patient was partially disabled for one month.

CLASS 3.—Insect bites and parasites:

CASE 1.—C. L., a white man aged 31, a schoolteacher, was seen for a dermatitis of the left leg.

History.—The patient went fishing six weeks before and noticed that evening several red spots on his leg. He assumed that they were due to chiggers. A solution of blue vitriol was applied, and the following day the area presented an angry appearance. During the ensuing weeks he applied a perfumed

tar, a red liquid, a mentholated salve, a white tar, a talc cold cream and a green liquid.

Examination.—The skin over the middle third of the left leg showed an intense inflammatory reaction, and throughout were patches of vesicles intermingled with pustules. There were also scattered areas of gangrene, quarter (24 mm.) to pea size. The less involved skin was stained a bluish green.

Course.—Saline compresses changed four times daily for five days produced a remarkable reformation. The gangrenous areas sloughed, leaving punched out erosions. The pustules and stains had disappeared. A colloidal clay paste was applied for one week and then discontinued. Within less than three weeks the involution was about complete.

Laboratory Tests.—Routine examinations were negative. All patch tests were negative except for the blue vitriol and the perfumed tar. Both showed a cluster of vesicles and an intense inflammatory reaction. Each persisted over a week.

Comment.—There was partial disability of the left leg for nine weeks.

CASE 2.—M. W., a white woman aged 42, a clerk, was referred for a dermatitis of the neck and face.

History.—Two weeks previously the patient was told that she had some pimples on her neck that looked like insect bites. A friend advised a salve containing picric acid. After she had used this salve on the neck, chin and mandibular region of the face a redness appeared, slowly increasing in intensity. For the last ten days a mentholated petrolatum was used.

Examination.—The areas to which the salve had been applied showed a pronounced erythema with considerable edema. Many of the hair follicles over the back of the neck showed pustules. The middorsal area of the neck was hard and tender to palpation, with concomitant signs of an incipient carbuncle. The condition of the patient necessitated hospitalization.

Course.—Saline compresses led to a prompt clearing of the inflammation and edema. The folliculitis of the neck slowly subsided. After six days of compresses the carbuncle drained profusely. The patient left the hospital on the eighth day.

Laboratory Tests.—Routine examinations were negative. A twenty-four hour urine specimen was negative and the sugar tolerance was within normal limits. After twelve hours the patch test with the salve said to contain picric acid showed a 4 plus reaction. The reaction at the site persisted over a week. The other patch tests were negative.

Comment.—It is interesting that there were no signs of a carbuncle until eight days after the picric ointment had been applied.

CLASS 4.—Chronic dermatoses characterized by remissions and exacerbations.

CASE 1.—L. W., a white man aged 30, a dry cleaner, was referred for dermatitis of the right thumb.

History.—The patient was told three months before that he had a fungous infection of the thumb. A sulfonamide ointment was applied for a week, later a "cream" and for the past eight weeks a tar salve.

Examination.—The nail was hypertrophic, showing precipitous transverse ridges. The distal portion of the nail was separated from the plate about one third its length by a mass of yellowish debris. The dorsal skin of the thumb showed an inflammatory reaction with sufficient edema to cause this thumb to appear about one fourth larger than the left.

Course.—Saline compresses were applied and changed three times daily. After three days the cuticle and subungual region were scraped free of dead epithelium and impacted tar. A colloidal clay paste was used for one week. By this time the edema had lessened, the inflammation was subsiding and within three weeks the thumb was about normal. Normal nail growth was visible within four weeks.

Laboratory Tests.—Routine examinations were negative. Repeated scrapings for fungi were negative. All patch tests were negative except the tar salve, which showed a 2 plus reaction. The latter persisted for eight days.

that the fertilized egg usually implants on one of the two relatively flat uterine walls either anterior or posterior—that the placenta practically covers one of the two seen for because of that becomes quite readily displaced in a lateral soft tissue x-ray film.

History.—In this film in labor was mainly due to before he applied a salve Dippel and Brown,¹⁹ and it same salve had done wonder that it should be one of the the toes were swollen, and withy in labor. This film necessary. While in the hospital a bath of the fetus and, if of an organic mercurial, potassium permanganate is posterior, bath solution and a mercury ointment were applied, shows the left the hospital voluntarily after two weeks. becomes

Examination.—The toes and dorsal surface of the foot showed an intense inflammation with edema, weeping and crusting. The foot was stained a brownish black.

Course.—The patient was hospitalized for three days. The foot was elevated and the saline compresses were changed every hour. Beginning the fourth day a colloidal clay lotion was applied and discontinued after ten days. The middorsal portion of the foot showed an irregular area of slate colored pigmentation. The patient was wearing a shoe for the first time in six weeks. The pigmentation has persisted.

Laboratory Tests.—Routine examinations were negative. Three attempts to demonstrate fungi were unfruitful. The trichophytin and iodimycin tests were negative (forty-eight hours). All patch tests were negative except the tincture of the organic mercurial and the mercury ointment. These were 4 plus and produced a flare of erythema around the site and a macular dermatitis involving the arms and trunk. The dermatitis persisted for three days and the patch tests for over a week.

Comment.—There was total disability of the left foot for eight weeks, over two of which were spent in the hospital.

COMMENT

These case reports, selected from those observed, illustrate the cause of overtreatment dermatitis. The initial skin lesion registered complaint—increased erythema, edema and weeping—from the first application. Instead of the preparation being removed something else was applied, and the more the lesion complained the greater was the variety of applications applied. The admixture of antipruritics, antiseptics, astringents, rubefacients, keratolytics, fungicides, oxidizing agents and reducing agents in various vehicles unleashed on innocent lesions a veritable chemical maelstrom. The lesions do weep, in fact huge tears of chemical irritation.

It should be emphasized that the saline compress and the colloidal clay were not instrumental in healing the dermatitis. The former served to free the skin of irritants, the latter a covering while the skin healed. The continuation of either beyond their period of usefulness would have complicated and delayed the involution process.

The creation of the Council on Pharmacy and Chemistry served to rob of glamour the old oral concoctions and potions; it sifted the wheat from the chaff. Today oral drugs are fairly well defined. Dosage, indications and contraindications are familiar to all. There is constant vigilance for signs and symptoms of toxicity. Topical drug therapy, on the other hand, is generally speaking still in the stage of "try—stop—try." In the treatment of skin disease the admonition Try this preparation, if no improvement try this one, and so on, is familiar. It is this practice that causes overtreatment dermatitis. In skilled hands this "try—stop—try" method is controlled. In unskilled hands, which treat the major portion of acute dermatoses, too much treatment often results. It is the acute derma-

tosos that require the greatest treatment control and consideration. It seems that a concise chemical and pharmacologic evaluation of drugs used on the skin might lead to a decline of the incidence of overtreatment dermatitis. That is another sifting of the wheat from the chaff and this time to rob of glamour the cutaneous drugs, irrespective of the real or fancied virtues of the particular vehicle.

SUMMARY

The tendency of persons to apply remedies on skin lesions can be used to great advantage by the physician. The technic of the patch test is not difficult.³ The procedure of the past-treatment patch test furnishes the following data:

1. It reveals the presence of an irritant or sensitizer in the remedies applied.
2. It permits a "cooling off" period, as it were, to observe the effects on the lesion of the simplest of measures.
3. It permits prescribing a preparation avoiding the pitfalls of those already used.
4. Finding an irritant or sensitizer in a medicament often aids in determining the original source of the dermatitis. Example: The past-treatment patch test with a tar salve was strongly positive. The patient then recalled that the dermatitis appeared after tarring a roof.
5. A positive patch test to a substance in a remedy invites tracing the distribution of the substance in normal trade channels which may disclose additional contacts and help in deciding the occupational or non-occupational etiology of the dermatitis.

CONCLUSIONS

If remedies have been applied to a skin lesion, the past-treatment patch test provides data of etiologic, diagnostic and therapeutic importance. For the most part patients have shown an eager interest in uncovering and comprehending the evils of their own doing. The manufacturers of proprietaries have been most cooperative in furnishing individual ingredients. The simple expedient of the past-treatment patch test would lessen the incidence of overtreatment dermatitis, thereby avoiding unnecessary disability, even needless hospitalization.

Medical Facilities on the Gilbert, Ellice, Ocean and Nauru Islands.—Prior to the war the public health, medical and hospital facilities in the Ellice, Gilbert, Ocean and Nauru islands were considered to be adequate for the health and medical requirements of the people. Public health was under the direction of English health officers, who were assisted by several native medical practitioners and many locally trained dressers. Rainfall and wells furnish the only fresh water available on the islands; the supply is limited, especially in the southern Gilbert Islands. Systems in which sewage is water borne and a few chemical systems were in operation at the foreign establishments on Ocean and Nauru islands and in a few of the foreign homes. In other foreign homes the pan and bucket system was used. Most of the natives use over the sea latrines built on the beaches below high tide mark and connected to the shore by bridges, or they use the beach itself. Practically no supplies of food excepting coconuts and a few dishes can be obtained locally. Medical and hospital supplies are imported.—Simmons, James S.: Global Epidemiology, Philadelphia, J. P. Lippincott Company, 1944.

THE INFLUENCE OF PLACENTAL SITE
ON FETAL PRESENTATION

RICHARD TORPIN, M.D.

AUGUSTA, GA.

Occiput posterior presentation of the fetus since its designation and study as such by Baudelocque, Capuron and Naegele more than a century past has aroused increasing interest among obstetricians. Because of high incidence and poor management it probably has caused more obstetric disorder than any other single condition. Until the introduction of x-ray study of the size and shape of the pelvic cavity early in this century and of the study of the contour of the uterine cavity, only recently begun, all theories in regard to the etiology of occiput posterior presentation were speculation.

Occiput posterior presentation may be classified into three categories:

1. Primary occiput posterior presentations occurring at the onset of labor which rotate in labor to occiput anterior presentations.
2. Those which may rotate to cephalic transverse presentations and become stationary, so-called cephalic deep transverse arrests.
3. Those that are delivered as occiput posterior.

The etiology of these three types should be considered separately. In the German literature the incidence of occiput posterior is usually very low, 1 to 2 per cent, but, as Siedentopf¹ states, they recognize only those cases which fail to rotate. Williams and Stander² give the incidence as 11.3 per cent, or 618 cases in 5,488 labors. Williams stated that early in labor the incidence may have been much increased over these figures, because some may have rotated anteriorly before the examination. Danforth³ studied 1,565 private patients, examined each in labor and found an incidence of occiput posterior presentations in 27.1 per cent. Melhado's⁴ incidence at the Royal Victoria Hospital, Montreal, was 13.8 per cent. Cosgrove⁵ found the incidence 5.1 per cent in 15,000 consecutive deliveries but stated that it probably was far too low, because many patients were admitted too late for the primary presentation to be noted. Furthermore, the diagnoses were made in association with routine rectal examinations. Very likely, as Crotty⁶ states, 20 per cent of all labors with cephalic presentation begin with the occiput posterior. Caldwell, Moloy and D'Esopo⁷ in two hundred x-ray studies in labor found that occiput posterior presentation made up 20 per cent of the total. The true figure will be ascertained only by a large series of x-ray films taken at the onset of labor. A satisfactory single film is one taken of the soft tissues laterally. In this the true presentation is almost infallibly recorded. In this small series of 500 such films taken in the first stage of labor, the incidence of occiput

From the Department of Obstetrics and Gynecology, University of Georgia School of Medicine.

Read before the Section on Obstetrics and Gynecology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

posterior presentations was 24 per cent. This included all cases in which the occiput deviated as much as 5 degrees posterior to the true transverse.

In relation to parity, Melhado, in an analysis of 976 cases during a period of six years, found occiput posterior presentation in 513 primiparas and in 463 multiparas. Lewis⁸ in 728 cases found it to occur 305 times in primiparas and 423 in multiparas. Plass⁹ found practically equal numbers in primiparas and in multiparas in 635 instances.

In regard to whether the occiput is directed posteriorly to the right or to the left, all writers agree that the right prevails over the left. Plass, in his classic paper in 1916, found the relative incidence to be 437 right to 181 left. Danforth found 386 right to 57 left, Melhado, 619 right to 357 left, Lewis, 490 right to 238 left, Mast¹⁰ 189 right to 16 left and Vaux¹¹ 212 right to 118 left.

Several accurate x-ray studies have been made of the fetal presentation in relation to the pelvic architecture. The first in 1920 was by Fabre and Trillat,¹² who showed 12 pelves with high assimilation of the vertebrae and long anteroposterior diameter. In 7 of these there occurred persistent occiput posterior presentation. In 1933 these findings were confirmed by Thoms,¹³ who showed the pelvic cavity measurements in association with 12 persistent occiput posteriors. In 5 of these the anteroposterior diameter averaged 1.25 cm. longer than the transverse diameter of the inlet. In the other 7 the anteroposterior diameter averaged only 0.75 cm. less than the lateral.

A more detailed study by the stereoroentgenographic method was reported in 1934 by Caldwell, Moloy and D'Esopo¹⁴ in a review of 200 labors, all with cephalic presentation. They revealed a distinct inclination for the fetal head to engage with its anteroposterior diameter parallel to the widest diameter of the inlet, so that in gynecoid and android pelves with wide inlets the tendency was for occiput transverse presentations. In pelves with long anteroposterior diameter and relatively narrow side walls, i. e. anthropoid pelves, there was a definite tendency for the head to engage either occiput posterior or occiput anterior. The detailed findings are revealed in table 1.¹⁵

In 1941 D'Esopo¹⁶ by the same method reported the study of 100 labors with occiput posterior presentations of the fetus, and in 83 per cent he noted some degree of narrowing of the forepelvis and ample anteroposterior diameter, i. e. anthropoid pelves. In the other 17 per cent, as a rule, the inlet was either very large or round.

In the past decade there has been a growing appreciation of the shape of the pregnant uterus. It has been shown to be roughly pyramidal, with the breadth of the fundus wider than its greatest anteroposterior diameter in such a manner that the horns are usually well shown even at term. It has also been revealed¹⁷

that the fertilized egg usually implants on one of the two relatively flat uterine walls either anterior or posterior and that the placenta practically covers one of the two walls and because of that becomes quite readily distinguishable in a lateral soft tissue x-ray film. The appreciation of this film in labor was mainly due to Snow and Powell¹⁸ and Dippel and Brown,¹⁹ and it has been so well established that it should be one of the routine technics of radiography in labor. This film shows definitely the presentation of the fetus and, if cephalic, it reveals whether the occiput is posterior, transverse or anterior. This film usually shows the shadow cast by the placenta and thereby becomes valuable in such conditions as placenta previa and premature separation of the normally implanted placenta. It shows the exact descent of the presenting part and degree of engagement or nonengagement. Snow and his associates noted that, as a rule, the fetus faced the placenta, and this fact was observed so frequently in our routine studies made on all primiparas over a period of years that it was decided to study the relationship of the placental site to the fetal presentation. The series comprises possibly 600 lateral soft tissue films taken, usually in the first stage of labor, mainly, but not exclusively, in primiparas. Unless the placenta on either the anterior or the posterior wall was distinctly shown, the film was discarded, leaving 500 films which compose the details of this paper. Three hundred and

TABLE 1—Engagement in Gynecoid, Android, Anthropoid and Combined Types

	Gynecoid	Android	Anthropoid	Combined

Anterior oblique position	20	8.5	17.0	16.0
Direct occipitoanterior position	1	...	17.0	5.5

sixty-three of these films have been studied and reported previously.²⁰ This paper acts as a check on the previous findings, which altered the commonly accepted conclusions so much as to warrant further confirmation or denial.

Previously Pendleton²¹ and Melhado suggested that possibly the location of the placenta might have some influence on the fetal presentation, and it is well known that when the placenta is low lying, as in placenta previa, there is a tendency for the presenting part to fail to engage well.

The shape of the bony pelvic cavity has considerable effect on the mechanism of labor in occiput posterior presentation. Hanson²² in 1934 drew attention to the narrow midpelvis as revealed by inward protrusion of the ischial spines as a cause of persistent occiput posterior. He showed that primary occiput posterior occurring with a narrow midpelvis became persistent in 20.9 per cent of instances but that primary occiput posterior rotated spontaneously in all but 1.6 per cent when the midpelvis was wide.

In 1935 Caldwell, Moloy and D'Esopo,²³ writing on the mechanism of labor, came to the same conclusions in regard to persistence of occiput posterior presentation, and they gave several illustrations in all of which there were a narrow midpelvis and inward protruding ischial spines in, as a rule, the anthropoid type of pelvis.

In our clinic it is the rule to care for the woman in labor to such an extent with the use of fluids, dextrose, oxygen and sedation (and blood transfusions, if necessary) that all but a very few deliver spontaneously.

a narrow midpelvis, as brought out by Hanson, Thoms and Caldwell and their associates. But in the other 6 there was found in each case a justomajor pelvis or a very small fetal head in a normal pelvis. In the latter groups apparently there was little in the fetopelvic relationship to force the head to rotate and, as a consequence, it delivered eventually without rotation. This then is an additional factor in the etiology of persistent occiput posterior.

The accompanying chart reveals the collected evidence: There were in all 500 patients, 234 white

To the left of the midline the figures are represented with the placenta on the anterior uterine wall, to the right of the midline the placenta is represented as on the posterior uterine wall. The cephalic presentation is illustrated with the total number of such presentations tabulated below each figure. The placenta was on the anterior wall in 83 instances and on the posterior wall in 104.

Otherwise, if forceps are used in more than 1 or 2 per cent of all deliveries, the obstetrician is in no position to state whether a given patient would or would not have delivered. Now with this sort of management every so often a fetus will be delivered with the occiput posterior. A record of all these cases is kept and a correlation then is made with all facts known, including x-ray study of the pelvis. From a study of 12 consecutive cases it was revealed that in 6 there was associated

women and 266 Negro women. (All breech cases, all indistinct films and those in which the placenta was not definitely outlined on either wall were excluded.) Among the white women, 111 placentas were located on the anterior and 123 on the posterior wall. Dippel and Brown noted equal distribution between the two walls. We, however, over a period of years have made comment on the fact that our series had more on the posterior wall and we were of the opinion that 40 per cent were anterior and 60 per cent posterior. This study reduces the difference to 47 per cent on the anterior and 53 per cent on the posterior wall, a further

23. Caldwell, W. E.; Moloy, H. C., and D'Esopo, D. A.: Further Studies on Mechanism of Labor, *Am. J. Obst. & Gynec.* 30: 763 (Dec.) 1935.

reduction over the previous study of 45 per cent to 55 per cent.

From analysis of the data noted in the chart it becomes apparent that in 500 cases there were 239 (46.5 per cent) occiput anterior presentations, 140 (29.5 per cent) occiput transverse presentations²⁴ and 119 (24 per cent) occiput posterior presentations at the time of making the films in the first stage of labor. Still further analysis reveals that there were 243 cases with the placenta situated on the anterior wall of the uterus. Among these, 82 (33.6 per cent) were associated with occiput anterior presentation of the fetus, 80 (33 per cent) with occiput transverse and 81 (33.3 per cent) with occiput posterior presentation. On the other hand 257 placentas were situated on the posterior wall, 151 (59 per cent) occiput anterior, 68 (26.5 per cent) occiput transverse and 38 (14.5 per cent) occiput posterior. Thus when the placenta was anterior the incidence of occiput anterior presentation was approximately two thirds of what it was when the placenta was posterior, and when the placenta was anterior the incidence of occiput posterior presentations was more than twice what it was when the placenta was posterior.

An additional correlation was made of the fetal presentation in relation to the location of the placenta, as illustrated in the nine anatomic plates in the Atlas of Anatomy of Clinical Obstetrics by Canton and Gonzales of Buenos Aires, Argentina, 1910. In 4 cases the placenta lay on the anterior wall of the uterus and the fetus in labor presented occiput anterior once, occiput posterior once and occiput transverse twice. In 5 cases the placenta lay on the posterior wall and the fetus in labor presented occiput anterior in all 5 cases. In this small series, then, only once did the occiput lie toward the placenta.

Elsewhere²⁵ it has been shown that the pregnant uterus is like an irregularly globular bag, wider at the fundus than at its anterior posterior diameter. Now the cavity of this bag has been shown usually to have two

TABLE 2.—Site of Placenta

Presentation in First Stage of Labor	Anterior (243)	Posterior (257)
Occiput anterior	82 (33.6%)	151 (59%)
Occiput transverse	80 (33%)	68 (26.5%)
Occiput posterior	81 (33.3%)	38 (14.5%)

essentially foreign bodies pressing into it, either from one anterior or posterior wall or from both; one of these is the lower lumbar maternal spine and the other is the bulky placenta. Calkins²⁶ intimates that the full urinary bladder may also be a factor. The fetus, on the other hand, is essentially a parallelopiped with one concave ventral surface opposing a convex dorsal surface. When this geometric figure lies in the uterus, the great tendency is for the convex dorsum to lie opposite or at least not toward the greatest indentation, which is no doubt the lumbar spine. (This is very evident at any full term autopsy.) However, the placental foreign body probably has a tendency to alter this position accentuating its effect, if it happens to lie on the same wall (the posterior) as the promontory, and a tendency to cancel the effect if it lies on the anterior wall.

²⁴ These are exact occiput transverse presentations. If they deviated more than 5 degrees they become occiput anterior or occiput posterior.

CONCLUSIONS

1. The great majority of placentas are located on the anterior or posterior wall of the uterus.
2. The ratio found in this study was 47 anterior to 53 posterior.
3. The placenta located on the anterior wall had a definite tendency to the production of occiput posterior presenting fetuses. Mathematically, when the placenta was anterior the chance for occiput posterior presentation of the fetus was double what it was if the placenta was posterior, 33.3 per cent to 14.5 per cent.
4. The placenta located on the posterior wall had an increased tendency to produce occiput anterior presentation in the fetuses. In this incidence, when the placenta was on the posterior wall the chance of the presentation being occiput anterior was nearly twice what it was when the placenta was anterior, 59 per cent to 33.6 per cent.
5. The incidence of occiput transverse presentation of the fetus in the first stage of labor was 26.5 per cent if the placenta was located on the posterior wall and 33 per cent if it was located on the anterior wall.

A SIMPLE CLINICAL METHOD FOR THE ASSAY OF PENICILLIN IN BODY FLUIDS

AND FOR THE TESTING OF PENICILLIN SENSITIVITY OF BACTERIA

JEAN V. COOKE, M.D.

ST. LOUIS

Many of the methods for penicillin assay were devised and used primarily for testing solutions during the production of penicillin and are not easily applicable to the determination of titers of body fluids in patients under treatment. These have been reviewed by Foster and Woodruff,¹ the classic test of Florey² being in most common use. Of the studies made on body fluids, the method described by Rammelkamp³ involving the use of serial broth dilutions and a strain of hemolytic streptococcus was used by Rammelkamp and Keefe.⁴ Rosenberg and Sylvester⁵ have used Foster's method⁶ of serial broth dilution with *Staphylococcus aureus* and turbidimetric measurements, while Romansky and Rittman⁷ have used a method described by Rake and Jones⁸ based on the property of the inhibition of hemolysin production of streptococci by penicillin. The procedure to be described here is believed to be simpler than some of the other methods mentioned, is easily applied to the study of body fluids for penicillin titer, and utilizes only materials and methods familiar to all

bacteriologic technicians. In addition it can be readily used for determination of the penicillin sensitivity of various strains of *Staphylococcus aureus* or other organisms. A large number of titrations on blood serum and other body fluids, including spinal fluid, pleural and ascitic fluids and subcutaneous edema fluid, have been performed, and the results have appeared to be quite consistent. They will be summarized and discussed in a separate report.⁹

The method consists essentially in determining the lowest concentration of penicillin which will produce complete inhibition of growth of a standard strain of *Staphylococcus aureus* on a plain agar Petri plate and is carried out in the following manner:

Ordinary tryptose agar plates with a depth of 5 to 6 mm. are allowed to dry until all free moisture and condensation fluid have evaporated. On the bottom of the plate near the center, an area 2 by 5 cm. is marked on the glass with a wax pencil, and on the surface of the agar over this area is measured 0.1 cc. of the fluid to be tested, which is evenly spread over the 2 by 5 cm. "window." The plate is then placed in the ice box, care being taken that the surface remains flat, since tilting will spread the material beyond the

unit per cubic centimeter. In routine tests using 0.1 cc. of blood serum or other body fluid, if complete inhibition occurred, the penicillin titer was considered at least 0.2 unit per cubic centimeter. A more exact titer could be obtained by diluting the smallest amount

TABLE 1.—Scheme for Dilution of Body Fluid to Titrate Penicillin Content with *Staphylococcus Aureus* 209P

Tube Number	Serum or Other Fluid	Isotonic Saline Diluent	Penicillin Titer Units per Cc. When 0.1 Cc. Is Used in Test
1.....	0.1	...	0.2
2.....	0.2	0.2	0.4
3.....	0.1	0.2	0.6
4.....	0.1	0.3	0.8
5.....	0.1	0.4	1.0
6.....	0.1	0.5	1.2
7.....	0.1	0.6	1.4
8.....	0.1	0.7	1.6
9.....	0.1	0.8	1.8
10.....	0.1	0.9	2.0

of the fluid producing such inhibition. A simple dilution scheme is illustrated in table 1 by which titers from 0.2 to 2.0 units per cubic centimeter may be determined. In routine tests only tubes 1, 2, 5 and 10, corresponding to titers of 0.2, 0.4, 1 and 2 units per cubic centimeter, were used and, if desirable, a later test to determine a more exact titer.

Certain general statements about the method may be made.

The agar plates used must be dry and free from visible moisture, since otherwise the test fluid or the inoculum will spread irregularly over the surface.

A rubber stamp with which the 2 by 5 cm. "window" may be outlined in ink on the bottom of the dish is convenient and saves much time in carrying out the tests.

The use of a "window" 2 by 5 cm. in size on the agar plate for the fluid to be tested is necessary, because 0.1 cc. of fluid is readily absorbed by the agar over such an area while with more fluid or a smaller area the absorption is much slower. Occasionally

in fluids of low titer 0.2 cc. of the undiluted material (which would show a reading of 0.1 unit per cubic centimeter) has been used, but this requires a longer "drying period."

TABLE 2.—Scheme of Penicillin Dilution for Testing Sensitivity of Bacteria

Dilution or Plate Number	Penicillin Solution, Cc. (2 Units per Cc.)	Isotonic Solution of Sodium Chloride, Cc.	Units of Penicillin in 0.1 Cc.
1.....	0.1	...	0.2
2.....	5.0	5.0	0.1
3.....	4.5	5.5	0.09
4.....	4.0	6.0	0.08
5.....	3.5	6.5	0.07
6.....	3.0	7.0	0.06
7.....	2.5	7.5	0.05
8 ..	2.0	8.0	0.04
9 ..	1.5	8.5	0.03
10.....	1.0	9.0	0.02

It is important to keep the plates flat after receiving 0.1 cc. of fluid to be tested, because if tilted this fluid will spread beyond the 2 by 5 cm. window.

Absorption of the fluid by the agar does not occur more rapidly at incubator than at ice box temperatures, and the titers obtained by incubating at 37 C. tend to be slightly lower than when the refrigerator is used.

Fig. 1.—Complete inhibition (plate 1) of growth of a strain of *Staphylococcus aureus* by 0.03 unit of penicillin in the 2 by 5 cm. "window" and the lack of inhibition with 0.02 unit (plate 2).

marked area. After two to three hours the 0.1 cc. of fluid will have been absorbed into the agar in the 2 by 5 cm. window, leaving a dry surface. Inoculation of the prepared plate is then made by placing a large loopful of the broth *staphylococcus* culture on the surface of the plate at a short distance from the window and, with a sterile wire or thin glass rod bent at a right angle, the inoculum is lightly spread across the window in the form of a band about 1 centimeter wide. After incubation, the growth which develops along this band of inoculation stops sharply at the edges of the 2 by 5 cm. window if a sufficient concentration of penicillin was present in the fluid tested to inhibit the strain of *staphylococcus* used (fig. 1).

In the standardization of the method, tests of a number of strains of *Staphylococcus aureus* showed that the strain 209P,¹⁰ one of those in use by many laboratories, had the highest degree of penicillin sensitivity by this method. With this organism, growth was regularly completely inhibited by 0.02 unit of penicillin in 0.1 cc. and not by 0.01 unit. This has been expressed as 0.2

9. Cooke, J. V., and Goldring, David: The Concentration of Penicillin in Various Body Fluids During Penicillin Therapy, J. A. M. A. 127: 80 (Jan. 13) 1945.
10. This organism was obtained from the Food and Drug Administration together with some standard penicillin calcium through the kindness of Dr. Albert C. Hunter, director of the Bacteriological Division.

The p_H of the culture mediums routinely used has been 6.8 to 7.0. Using a standard penicillin, tests showed no difference between mediums with p_H of 6.5 and 7.0, but mediums with a p_H of 7.5 were less satisfactory.

For the standard *Staphylococcus aureus* (209P), a young 18 to 24 hour culture in broth has been used regularly, but the strength of the inoculum employed is apparently of little importance since the same complete inhibition occurs on the plate when the growth is heavy and confluent as when the culture is diluted so that only scattered discrete colonies grow. As a routine, a loopful of 1:10 dilution has been quite satisfactory for the inoculum.

No loss in penicillin titer in body fluids has been noted after twenty-four hours when kept at 4 C., but a definite decrease occurs after forty-eight hours.

MODIFICATION OF METHOD BY USING MULTIPLE INOCULUMS

The procedure described has been used in the study of body fluids from a number of cases reported separately.⁹ In observations on the penicillin sensitivity of various strains of *Staphylococcus aureus* which will be

of sensitivity from 0.02 to 0.1 unit in steps of 0.01 unit of penicillin, the three selected seemed best suited for routine clinical tests.

The photographs in figure 2 illustrate the appearance of such a test made on blood of an infant one hour after administration of 5,000 units of penicillin intramuscularly. Plate 1 had 0.1 cc. of undiluted serum, plate 2 0.1 cc. of serum diluted 1:1 and plate 3 0.1 cc. of serum diluted 1:2. The three strains mentioned and sensitive respectively to 0.02, 0.04, and 0.05 unit of penicillin were inoculated on each plate. In plate 1 all are inhibited, showing that more than 0.05 unit was present in the 0.1 cc. of serum, and the reading was more than 0.5 unit per cubic centimeter. Plate 2, with 0.05 cc. of serum, shows inhibition of the 0.04 unit strain (20) but not of the 0.05 unit strain (19), so that the reading is more than 0.08 but less than 0.1 unit, or 0.8 unit of penicillin per cubic centimeter. In the third plate, with 0.033 cc. of serum only the 0.02 unit strain (209) is inhibited and would be read more than 0.6 unit and less than 1.2 units.

This modification of the original method has simplified the examination of body fluids for penicillin and has given a somewhat more accurate titer.

Fig 2—Penicillin assay of blood (serum) with 0.1 cc (plate 1), 0.05 cc (plate 2) and 0.033 cc (plate 3), tested with *Staphylococcus* 19 (sensitive to 0.05 unit), 20 (sensitive to 0.04 unit) and 209 (sensitive to 0.02 unit). The serum contains more than 0.8 but less than 1.0 unit per cubic centimeter.

given later in this report, it was found that many of the strains tested had different degrees of sensitivity to penicillin and that this sensitivity of any individual strain remained constant. It was possible, therefore, by using simultaneously several strains of *staphylococcus* of different grades of sensitivity to penicillin to simplify the penicillin titration of body fluids. Three strains were selected for routine tests, the first (No. 19) being inhibited in 0.1 cc. by 0.05 unit of penicillin but not by 0.04 unit, the second (No. 20) being inhibited by 0.04 unit but not by 0.03 unit, and the third (209) being inhibited by 0.02 unit and not by 0.01 unit. When 0.1 cc. of the fluid to be tested is used in the plate and a separate inoculum of each of these three strains is streaked across the 2 by 5 cm. window, separate readings of 0.2, 0.4 or 0.5 unit per cubic centimeter are possible from a single plate. If a second plate using 0.1 cc. of a 1:1 dilution of the fluid is similarly inoculated, the readings are 0.4, 0.8 or 1.0 unit per cubic centimeter. Thus with only two plates, the ranges of 0.2 to 1.0 unit per cubic centimeter are possible, and for higher values an additional dilution would be necessary. Although, as will be noted later in table 3, strains of *Staphylococcus aureus* were available with a range

APPLICATION OF METHOD TO TESTING PENICILLIN SENSITIVITY OF BACTERIA

Variations in sensitivity of various strains of *Staphylococcus aureus* have been described by Rammelkamp and Maxon¹¹ and by Spink, Ferris and Vivino¹² while Dawson, Hobby and Lipman¹³ have shown that strains of nonhemolytic streptococci differ considerably in penicillin sensitivity. The method for penicillin assay described lends itself readily to the determination of penicillin sensitivity of various organisms, since such titration of sensitivity of stock strains is a necessary step in standardization of the method for assay of unknown fluids.

The procedure adopted for routine penicillin sensitivity titration is as follows:

A small amount of standardized penicillin powder is accurately weighed in a sterile weighing bottle and diluted with sterile isotonic solution of sodium chloride

11 Rammelkamp, C. H., and Maxon, T. Resistance of *Staphylococcus aureus* to the Action of Penicillin, *Proc Soc Exper Biol & Med* 51: 386 (Dec) 1942

12 Spink, W. W., Ferris, V., and Vivino, J. J.: Comparative *In Vitro* Resistance of *Staphylococci* to Penicillin and to Sodium Sulfathiazole, *Proc. Soc. Exper. Biol. & Med.* 56: 207 (March) 1944

13 Dawson, M. H., Hobby, G. L., and Lipman, M. O.: Penicillin Sensitivity of Strains of Nonhemolytic Streptococci Isolated from Cases of Subacute Bacterial Endocarditis, *Proc Soc Exper Biol & Med.* 56: 101 (June) 1944

so that the solution contains 100 units of penicillin per cubic centimeter. A second dilution (1:50) is made to contain 2 units per cubic centimeter for use in the tests. Further dilutions are prepared according to the scheme shown in table 2. It will be noted that the dilutions are all made to a total volume of 10 cc., since it was felt that dilution errors were minimized by the use of a larger volume. For the tests 0.1 cc. of each dilution is spread over the 2 by 5 cm. window of an agar plate in the manner previously described and dried two to three hours in the ice box. Broth cultures of one to three separate strains may be inoculated on each plate if each culture is spread in a separate channel. After incubation, complete inhibition of growth in each strain will be found with a certain fractional unit of penicillin, but the next lower dilution with 0.01 unit less will show no inhibition. The smallest amount of penicillin producing inhibition has been considered the titer of peni-

Small amounts of standard penicillin calcium may be obtained from the Food and Drug Administration in Washington, D. C., sufficient for a moderate number of assays. It is advisable to prepare one's own standard from other penicillin sodium which may be available and which can be standardized by use of the penicillin calcium.

Penicillin sodium is more hygroscopic than the calcium salt, and the standard prepared must be kept free from moisture. An accurate analytical balance must be used, and the original dilution should be carried out with certified pipets.

SENSITIVITY OF STAPHYLOCOCCUS AUREUS TO PENICILLIN

In table 3 are shown the results of tests for penicillin sensitivity in 30 strains of *Staphylococcus aureus*. These include the 2 stock strains Oxford H and 209P, together with 28 strains isolated from various human sources, 12 from infections in adults and the remaining 16 from children. The mannite fermentation and coagulase test on each strain is also given. There was a definite variation in sensitivity of the various strains since 20 were completely inhibited by less than 0.1 unit, 7 required 0.1 unit and 3 more than 0.1 unit, the most resistant needing 0.4 unit. Many of the patients from whom the organisms were isolated were treated with penicillin, but from a careful review of their records no conclusion was possible regarding the relation of the sensitivity of the organism to the clinical effect of penicillin therapy. Only 6 of the 30 strains fermented mannite, while 21 were coagulase positive.

The fact that some strains of *Staphylococcus aureus* are inhibited only by a concentration of penicillin five to ten times as great as required for other strains may be related to the lack of clinical response to penicillin therapy in certain infections by the more resistant strains.

SENSITIVITY OF MENINGOCOCCI TO PENICILLIN

Seven strains of meningococci grown from the spinal fluid of infants and children with acute meningitis were tested. None of the patients were treated with penicillin, and all recovered with sulfonamide drug therapy.

The organisms had been grown on blood agar from two weeks to two months before the tests, and blood agar and serum agar were used in the titrations, which were repeated several times on each strain. In table 4 are shown the results of from three to eight penicillin titrations on different occasions with these organisms together with *Staphylococcus aureus* (209) as a control. The titers of the separate strains showed only minor variations on successive tests. This was considered to be due to differences in the mediums used on different occasions. There was a striking difference in the sensitivity to penicillin in the different strains, since some were inhibited by 0.04 to 0.05 unit, while two required 0.1 unit and two others 0.3 unit. In units of penicillin per cubic centimeter this variation would range from 0.4 to 3.0 units. The standard test strain of *Staphylococcus aureus* (209P) is apparently slightly less sensitive to penicillin on blood agar than on plain agar,

Fig. 3—Penicillin sensitivity titration with three strains of *Staphylococcus aureus*. Strain C is sensitive to 0.06 unit of penicillin, strain A to 0.05 unit and strain B to 0.04 unit.

cillin sensitivity. In figure 3 are shown four plates used in such a titration with three strains of *Staphylococcus aureus*. These "windows" of these plates had successively 0.06, 0.05, 0.04 and 0.03 unit of penicillin, and it will be noted that all strains were inhibited by 0.06 unit (plate 1), while with 0.05 unit (plate 2) strains A and B were inhibited but not strain C; with 0.04 unit (plate 3) only strain B was inhibited, and with 0.03 unit (plate 4) none were inhibited. The penicillin sensitivity of these strains would be considered 0.06 unit (C), 0.05 unit (A) and 0.04 unit (B) respectively. Actually these were strains 8, 19 and 20, shown later in table 3. The sharp end point between complete inhibition of growth and lack of inhibition with 0.01 unit less of penicillin is well shown in the titration (fig. 3).

For those who have not had experience with using standard penicillin, certain suggestions may be of value

since 0.03 unit was required on the former as against the usual titer of 0.02 unit on the latter.

The fact that some strains of meningococci are definitely resistant to penicillin offers an explanation of the recent report by Meads, Harris, Samper and Finland,¹⁴ who found 5 patients with meningococcic meningitis clinically resistant to penicillin therapy. They also found differences in penicillin sensitivity in four strains of meningococci tested.

SUMMARY

Tests on various strains of *Staphylococcus aureus* and meningococci by a method for assay of penicillin in body fluids have shown a considerable variation in penicillin sensitivity.

First English Surgeon.—John of Arderne (1307-1380) is the first English surgeon. Several of his manuscripts have been preserved and reprinted with a translation into modern English. One of these is on fistula in ano. He saw war service during the Hundred Years War. He practiced in London and in Newark. His practice was among the nobility and his fees were enormous; tradition says that sometimes his fees consisted of ransoms for knights who were held by the Turks after the Crusades. Since he took the ransom, the knights never got home. Possibly he is the model for Chaucer's Doctor of Physic.—Clendening, Logan: *Source Book of Medical History*, New York, Paul B. Hoeber, Inc., 1942.

PRESENT STATUS OF CHRONIC REGIONAL OR CICATRIZING ENTERITIS

H. L. BOCKUS, M.D.

PHILADELPHIA

Consummative treatment of any disease comprises the destruction of the causative agent and/or the complete removal of the resultant lesion when one exists. Obviously this situation does not maintain in chronic regional enteritis. A definitive etiologic factor has not been discovered and often the entire lesion, particularly in the mesentery, cannot be removed with safety. Furthermore, after wide surgical excision of the diseased segment of intestine and its mesentery recurrences frequently take place. Sufficient experience has accrued since the epochal contribution of Crohn, Ginzburg and Oppenheimer¹ in 1932 to justify an appraisal of the present state of our knowledge of this interesting and not too rare lesion of the intestine.

NONCONTROVERSIAL ASPECTS OF CHRONIC ENTERITIS

It is not difficult to prepare a ledger epitomizing our present knowledge of this disease and the degree of success which has been had in the management of it. There is general agreement concerning the following: (1) The gross morphologic character and histologic architecture of the advanced lesion is well understood; (2) it is the most common chronic severe inflammatory lesion which primarily affects the mesenteric small intestine of persons in the United States; (3) its clinical manifestations are protean, yet if the possibility of the disease is considered the diagnosis is usually not difficult, and (4) good immediate results are usually obtained either by resection of the lesion or by a short-circuiting anastomosis with transection of the bowel proximal to the lesion. Operation can be accomplished with a relatively low mortality.

I do not propose to discuss those aspects of chronic cicatrizing enteritis about which there is general agreement except to comment briefly on its incidence and its diagnosis.

Incidence.—Approximately 160 papers dealing with chronic regional enteritis are listed in the *Cumulative Index* during the years 1939 to 1943 inclusive. A further idea of the incidence of the lesion may be obtained when it is realized that Shapiro² in reviewing the literature in August 1939 tabulated 519 cases of regional enteritis occurring in patients on whom operative procedures had been performed.

In the Western Hemisphere climate seems to play a role in the incidence of regional enteritis. The disease is rare in the southern sections of the United States and in Central America and the coastal regions of the northern part of South America. Race does not seem to confer an immunity, although relatively few cases have been reported in Negroes. The sex incidence is not significant. Chronic regional enteritis may occur at any age from early childhood to late life, but the average age is somewhat less than 30 years.

From the Graduate Hospital of the University of Pennsylvania Read before the joint meeting of the Section on Surgery, General and Abdominal, and the Section on Gastro-Enterology and Proctology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

2. Shapiro, R.: Regional Ileitis: A Summary of the Literature, *Am. J. M. Sc.* 198: 269 (Aug.) 1939.

Clinical Manifestations.—Although the subjective and objective features of regional enteritis parallel to some extent the site and extent of the disease and the presence or absence of complications, the possibility of the existence of the disease must be considered in the presence of multifarious symptoms and signs. The duration of symptoms in my patients with ileitis and ileocolitis subjected to operation (19 cases) varied from three months to six years. The average was twenty-nine months.

Symptoms and Signs Suggestive of Acute or Subacute Appendicitis: Although usually antecedent symptoms of pain, diarrhea or distention have been present in those patients with chronic regional enteritis presenting a clinical picture suggestive of acute appendicitis, not rarely these phenomena have been insufficient to attract attention. Ofttimes operation is performed because of the acute onset of symptoms without resort to roentgen studies, so that the diagnosis is first made on opening the abdomen.

Persistence or Recurrence of Symptoms Following Appendectomy: Under these circumstances the occurrence of clinical features such as lower abdominal pain, distention and diarrhea should cause one to entertain the provisional diagnosis of regional enteritis. This disease should be foremost in the mind of the clinician if an external fistula appears following appendectomy.

Chronic Abdominal Abscess: Symptoms or signs suggestive of a chronic abscess in the pelvis or lower abdomen, particularly the lower right abdominal quadrant, constitute the principal clinical phenomena of an occasional patient with cicatrizing enteritis. Pelvic inflammatory disease or disease of the bladder is suspected as the primary diagnosis in some instances.³

Multiple Perianal Fistulas or Abscesses: Such lesions occurring in patients having diarrhea, abdominal distention, vague lower abdominal pain or unexplained fever should arouse suspicion. Indeed, 8 patients in a series of 114 (7 per cent) with regional enteritis reviewed by Jackman and Smith⁴ sought medical aid primarily because of anal fistulas.

Diarrhea: Chronic or intermittent diarrhea in association with abdominal pain of the peristaltic type constitutes the major clinical syndrome in many patients with regional enteritis. The symptoms may simulate those of ulcerative colitis, although the temporary relief afforded by a bowel movement, the tenesmus and the presence in the stools of recognizable blood and pus (commonly present in ulcerative colitis) is usually lacking in enteritis.

Abdominal Pain: Dull to moderately severe pain (often located in the lower right abdominal quadrant) of a chronic, intermittent character if associated with either diarrhea, borborygmus or abdominal distention, a palpable mass or low grade fever should cause one to exclude the presence of regional ileitis.

Intestinal Obstruction: Symptoms of chronic, recurrent or acute intestinal obstruction may be caused by regional enteritis. Usually a carefully taken history will disclose the antecedence of diarrhea, peristaltic abdominal pain and borborygmus. Nutritional edema may accompany obstructing enteritis, and the extensive retention of fluid in the tissues and body cavities may be the most impressive feature of the clinical picture.⁵

4. Jackman, R. J., and Smith, N. D.: Some Manifestations of Regional Ileitis Observed Sigmoidoscopically, *Surg., Gynec. & Obst.* 76: 444 (April) 1943.

Rare Manifestations: Rarely the patient with regional enteritis may seek treatment because of peritonitis induced by free or walled off perforation or melena⁶ or chronic fever of undetermined origin⁷ or symptoms and signs suggestive of abdominal carcinoma in the aged.⁸ In some cases the palpation of an ill defined mass may represent the first finding of consequence. The clinical manifestations of regional enteritis may be indistinguishable from those of intestinal neoplasms, granulomas, intestinal tuberculosis and lymphomatous lesions, although a positive diagnosis of enteritis based on clinical signs and roentgen study usually proves correct. In rare instances regional enteritis has simulated chronic intussusception, twisted ovarian pedicle postoperative adhesions, pelvic tumors and cysts and diseases of Meckel's diverticulum.⁹ Regional enteritis is discovered occasionally in the absence of any symptoms.⁹

Roentgen Findings: Expertly performed barium meal study of the small intestine together with a barium enema will usually cause one to suspect chronic regional enteritis if it is present. The roentgen characteristics of the disease have been adequately described. Except in patients with definite obstruction or those with symptoms simulating acute appendicitis or peritoneal irritation requiring immediate exploration, operation is not justifiable in the absence of evidence of a roentgen abnormality. In the presence of a chronic cicatrizing lesion, if the roentgen investigation is negative, the examination has usually been inadequate or the interpretation in error. A lesion incapable of showing some type of roentgen defect of the intestine is hardly one which would require laparotomy.

CONTROVERSIAL FEATURES OF REGIONAL ENTERITIS

Let me now review those features of the disease concerning which differences of opinion still exist. The cause of chronic cicatrizing enteritis remains obscure and present methods of treatment are not entirely satisfactory.

Etiology of Chronic Cicatrizing Enteritis.—Neither the immediate cause nor the site of primary attack of the etiologic agent has been established.

Immediate Cause: There is nothing to suggest that a virus is causative. Because of the granulomatous character of the lesion, Rodaniche, Kirsner and Palmer¹⁰ applied the Frei intracutaneous tests to 4 patients with regional ileitis, using both mouse and human antigens, with negative results. These investigators quoted 9 other cases from the literature, which were similarly investigated, with negative results. The serums of the patients of Rodaniche and her collaborators¹⁰ were devoid of neutralizing antibodies against the virus of lymphogranuloma venereum. Attempts to isolate virus from resected intestine and lymph gland by animal inoculation proved unsuccessful.

No proof has been supplied to indicate that the inflammatory reaction in chronic regional enteritis is initiated by an animal parasite. Bacteria are usually held responsible by most observers for the primary attack. The tubercle bacillus has not been isolated from the lesions. Although viewed in an isolated manner the histologic character of the lymphatic involvement resembles tuberculosis, the tendency toward regression of the histologic lesions without scarring or caseation excludes the presence of active tuberculosis. Because of this character of the histologic lesion, Hadfield and others have commented on its simulation of sarcoidosis. However, up to this time no evidence has been added to suggest that regional enteritis is actually sarcoidosis.

Felsen¹¹ has reported the occurrence of chronic regional ileitis as sequelae of acute bacillary dysentery in 3 patients. He also observed 29 instances of acute terminal ileitis in association with bacillary dysentery and states that he has not seen acute terminal ileitis with mesenteric lymphadenitis in any disease other than bacillary dysentery. Bisgard and Henske¹² recovered a dysentery bacillus from the right kidney and a hemolytic streptococcus from the peritoneal fluid and a mesenteric gland of a child with regional ileitis.

Infections induced by food poisoning may possibly be responsible for the occurrence of chronic stenosing enteritis. A young woman (C. R.) recently studied at the Graduate Hospital dated the onset of her abdominal complaints from the eating of "spoiled" turkey which caused transient symptoms in 4 other persons. Previous exploration in another hospital revealed chronic stenosing enteritis involving 5 feet of the terminal ileum. The abdomen was closed without anything being done. Films one year later revealed the same extensive involvement (fig. 1). It is possible that the organism responsible for the food poisoning of this patient may have caused the primary inflammation of the intestine which eventuated in the advanced state of bowel disease. All evidence points toward bacterial invasion as a primary or exciting cause of chronic regional cicatrizing enteritis. It is likely that the process may be initiated by organisms having a predilection for lymphatic structures.

Predisposing Causes: There are no known predisposing causes of the disease. The personality pattern of many of my patients with chronic regional enteritis has aroused my interest. I have encountered very few calm, phlegmatic persons with this disease. Many of them were emotional, sensitive, rather excitable people. At least 4 of 19 patients could be classified as severely psychoneurotic, and 2 of them had been treated for a year or more prior to admission with the diagnosis of neurosis. The most prominent personality traits were anxiety and emotional immaturity. It has seemed to me that emotional immaturity is even more pronounced in patients with chronic regional enteritis than in those with chronic ulcerative colitis. One of the patients was admitted to an asylum for the insane within one year after resection of the terminal ileum with the diagnosis of dementia precox.

External violence or trauma may have been related to the onset of regional enteritis in a case reported by Morlock, Bargin and Pemberton.¹³ As predisposing

causes of cicatrizing enteritis there is nothing to suggest a primary nutritional defect, an endocrinologic disorder or allergy, although both nutritional deficiency states and allergy occur in association with the disease. Either condition may be responsible for the exacerbation of symptoms and perhaps for conditioning the chronicity of the lesion.

Site of the Primary Histologic Lesion: Regardless of whether the primary attack of the etiologic agent occurs by way of the intestine or by way of the blood stream, the lymphatic structures are unquestionably involved early and extensively. It has been shown by Hadfield¹⁴ and others that, before the stage of definite cellular infiltration of the tissues, the submucosa shows pronounced thickening due to lymphoid hyperplasia and obstructive lymphedema. Very early the lymph nodes exhibit the same changes. The extent of mucosal ulcer-

Fig. 1 (case C. R.).—Roentgenologic study by Dr. Arthur Finkelstein (Graduate Hospital) showing extensive involvement of the ileum with cicatrizing enteritis three and three-quarter hours after barium meal.

ation is not always proportionate to the involvement of the lymphatics. The experiments of Reichert and Mathes¹⁵ add support to the significance of lymphatic damage in this disease. Pathologic changes quite similar to those of regional ileitis were produced in the ileum of experimental animals by obstructing the mesenteric and submucosal lymphatics with sclerosing substances.

Some observers believe that mesenteric lymphadenitis¹⁶ may be the primary lesion in cases of regional ileitis. Holman's case may be cited in this connection. The terminal ileum and cecum of a child 6 years of age were removed for regional enteritis. The mucosa

of the ileum, the appendix and the colon were intact at every point, but the lesion in the ileum was characterized by an extensive diffuse edema involving also the mesentery and regional lymph nodes. It was inferred that the process was primarily lymphatic in origin and that ulceration of the mucosa in other cases of regional

Fig. 2 (case J. C.)—Film exposed in May 1937 one hour after ingestion of barium. The small intestinal loops in the midabdomen are narrow and stringlike and retain very little barium. The more distal loops show some narrowing and pronounced abnormality of the mucosal pattern. The only loops found to be diseased at autopsy in 1943 were those in the midjejunum marked with arrows. The ileal loops, which appeared to be extensively involved in 1937, showed no evidence of disease in 1943.

enteritis may be secondary to obstruction and infection of the lymphatics. Surgeons have noted a diffuse inflammation of the terminal ileum in cases of primary lymphadenitis.¹⁷ Unfortunately the link between acute ileitis and chronic stenosing ileitis has not been proved. The literature still lacks evidence of adequately observed cases of acute terminal ileitis in which the typical stenosing, cicatrizing lesion subsequently developed.

Erskine¹⁸ examined 31 surgically removed appendices in which major involvement was of the outer coat and lymph structures. In 10 of these inflammation of the terminal ileum and regional mesenteric adenitis had been described by the operating surgeon. Pathologically a dilatation of the lymph sinuses of the appendix was noted. It was thought that primary damage of the regional lymph nodes had caused a consequent

damming back of normal drainage of the appendix and terminal ileum. Erskine ventured the thought that ileal involvement in chronic regional ileitis might depend on this back flow of infective agents from the mesenteric glands or that the septic content of the ileum, lacking proper drainage, set up the chronic inflammatory process. Incidentally lymph node cultures in 3 of his cases showed respectively hemolytic streptococci, colon bacilli and tubercle bacilli, yet in each instance the same histologic reaction was found in the wall of the appendix.

If the foregoing thesis is correct, the lesion which we know as nonspecific chronic regional enteritis could at times be induced by primary enteric or glandular tuberculosis. The primary tuberculous infection, although overcome, might leave in its wake permanent damage to the lymphatics with obstruction to drainage from the intestine, paving the way for the inroads of secondary infecting organisms. The following case is of interest in this connection:

In 1940 Bockus, Tumen and Kornblum¹⁹ reported that in November 1935 a boy aged 14 years showed roentgen evidence of a widespread cicatrizing stenosing enteritis involving a considerable portion of the jejunum and at least the upper half of the ileum. Tubercle bacilli were recovered from the feces on three separate occasions by Dr. F. Boerner during the course of the patient's first admission to the hospital. Acid fast organisms were never recovered subsequently. This boy was under our observation in and out of the hospital for a period

Fig. 3 (case J. C.)—Mass of jejunal loops adherent to one another and connected in three areas by fistulas. One of the diseased loops is opened to show the extensive disease of the mucosa and thickening of the bowel wall. It would appear that the disease of the ileum had undergone regression.

of eight years until his death in December 1943. At postmortem examination only about 3 feet of jejunum was involved in the typical stenosing lesion of chronic regional enteritis. Pathologically there was nothing to suggest acid fast infection past

or present. It is recognized that the finding of the tubercle bacillus on three occasions in the stools hardly warrants a diagnosis of primary enteric acid fast infection; nevertheless it justifies speculation concerning the significance of the tubercle bacillus in the initiation of the lesion. Another interesting feature at autopsy was the absence of any demonstrable evidence of involvement of the distal jejunum and proximal ileum. This entire segment of the bowel showed only atrophy of the bowel wall, undoubtedly due to long standing partial obstruction of the midjejunum. The mesentery of the distal jejunum and entire ileum was quite normal. Figure 2 illustrates the extensive involvement that was noted roentgenographically prior to April

extension of the disease, but also on the accumulation of experience with the various methods of therapy which have been tested. I should like to review my experience with patients who have undergone radical operative treatment (tables 1 and 2).

Chronic Terminal Cicatrizing Ileitis: Eleven patients with involvement varying in extent from 8 inches to 5 feet of terminal ileum were subjected to ileocolostomy (ileotransverse colostomy 10 cases, ileo-ascending colostomy 1 case) and resection in one or two stages, with one operative death, a mortality of 9 per cent. The

1941. The absence of postmortem changes except in the jejunum suggested that a number of feet of ileum, formerly diseased, underwent regression with return to normal (fig 3).

Both pathologic and clinical observations suggest that in many cases of regional enteritis the primary lesion is in the lymphatic structures and that no specific organism can be held responsible for the disease. One must conclude that the lymphatics often bear the brunt of the attack and that extension via the mesentery undoubtedly occurs.

Surgical Treatment.—A decision concerning the type of treatment to be instituted for the patient with chronic regional enteritis depends, not only on what is known of the etiology and pathology and manner of

remaining 10 patients are alive. Five of them are known to have a recurrence of the stenotic process proved by roentgen study (50 per cent). X-ray evidence of recurrence of the disease was obtained at intervals varying between one and one-half and four years following resection. One of the patients with recurrence is in good condition. The remainder are in fair shape, carrying on part time activities. A good result was obtained in only 45 per cent of 11 patients subjected to resection.

Regional (Not Terminal) Ileitis: Three patients were subjected to operation. In 2 instances resection with anastomosis of normal ileum was performed and in 1, an extensive case of segmental ileitis, approximately 5 feet of the terminal ileum together with the ascending colon were resected and an ileotransverse

colostomy performed. A recurrence of the disease has been detected by x-ray in all 3 patients at intervals varying from one to three and one-half years after resection. All of these patients are able to carry on part time activity without great discomfort.

All Cases of Ileitis (Terminal and Regional): Summarizing the data from both groups just cited, 14 patients were subjected to resection with one operative death (7 per cent). The 13 remaining patients are alive, but recurrences have developed in 8 of them, or 62 per cent.

It should be stated that in 3 of the 14 patients operation was absolutely essential because of almost complete obstruction in 2 instances and extensive infection associated with multiple fistulas in the third patient. All 3 patients are alive. Totally satisfactory results have been obtained in only 5 of 14, or 36 per cent of patients subjected to resection.

Ileocolitis: Five patients were operated on. In 4 instances the terminal ileum was involved and more than three fourths of the proximal colon. The terminal ileum and one third of the proximal colon were involved in the fifth patient. In 4 of the 5 patients the colonic involvement extended to the region of the junction of the descending colon with the sigmoid. In 1 instance

TABLE 2.—Radical Resection, Chronic Regional Ileitis and Ileocolitis

	No. of Cases	Operative Mortality, per Cent	Alive, No. of Patients	Recurrence, No. of Patients	Good Result, per Cent

				subsequent death	
Total cases.....	19	10	15	9	37

death occurred after the primary ileosigmoidostomy, which unfortunately was performed without transection of the ileum. In the remaining 4 patients ileosigmoidostomy and resection of the ileum and colon proximal to the anastomosis were carried out. In 1 it was performed in two stages, and in the remaining 3 a one stage procedure was used. An operative mortality occurred in 2 of the 5 cases (40 per cent), the second mortality following a one stage resection. Three patients survived operation, but 1 died three and three-quarter years later as a result of multiple external fistulas and peritonitis. The remaining 2 patients are in good health, four and eight years following the operation.

• Adding our experience with ileitis to that of ileitis combined with colitis, 19 patients were subjected to operation and good results were obtained in 7, or 37 per cent. Four of the patients have died, a mortality of 21 per cent.

Resection Compared with Other Therapeutic Procedures: If one should attempt to compare these results with those to be anticipated if medical management had been substituted for operation, one could conclude that 3 of the patients would have succumbed without resort to operation as compared with the death of 4 patients following operation. In 7 others it is unlikely that more favorable results would have obtained with conservative management in view of the extent of involvement and the presence of fistulas and other abnormalities. Consequently by any criteria 10 of the 19 patients would certainly have been no better off. This leaves 9 patients in whom the results to be anticipated by conservative management cannot be estimated.

It is doubtful if all 9 patients would have remained as well as 7 of them have been, following resection of the lesion. In order to decide this question of the advisability of radical operation versus conservative management in the absence of complications, one should know whether or not this chronic granulomatous process in the intestine and the extensive disease of the mesentery ever recede during the course of adequate medical management. It is possible in some instances that recession of the lesion may occur (see case J. C.), but experience with the disease up to this time would suggest that complete resolution rarely takes place.

In view of the experience with radical operation cited, one is tempted either to treat some patients conservatively, as suggested by Cutler,²⁰ or to abandon resection with ileocolostomy for some other more conservative surgical procedure. The experience cited by Marshall²¹ at the Lahey Clinic justifies a careful appraisal of the Mikulicz type of resection in the treatment of the terminal type of chronic regional enteritis. This operation was performed thirty-five times at the Lahey Clinic with only one death, which was attributed to embolism. Recurrences were reported in only 9.6 per cent of the cases. Twenty-one had been followed for a period of four years or longer. These results are certainly superior to those obtained in my series of cases with resection and internal anastomosis.

In 1939 Shapiro² surveyed the results obtained by short-circuiting operations performed one year or more prior to the time of his report on 88 patients with regional ileitis. The mortality in this series was 8 per cent, but the incidence of freedom from symptoms was only 30.6 per cent in spite of the relatively short period of follow-up observation. Perhaps some of the bad results in these cases were due to the lack of transection of the ileum distal to the anastomosis, since it was impossible to learn from the case reports how often this necessary procedure was carried out. Only 14 of 45 patients in the report by Brown and Donald²² remained well after short-circuiting operations. However, more recently Ginzburg and Garlock³ and others have looked with favor on a short-circuiting anastomosis with exclusion in preference to resection of the lesion. Ginzburg and Garlock performed this operation fifty-four times without an operative death and with only two subsequent deaths. They report only seven failures in the 54 patients so treated. If a longer period of observation confirms these excellent results it would appear that short-circuiting operation with exclusion is preferable to resection with internal anastomosis.

Perhaps one should refrain from operating on some patients with regional enteritis in the absence of extensive infection or obstruction in order to determine whether or not the infective process will subside and some degree of resolution occur, as it does occasionally in chronic ulcerative colitis. Patient C. R., previously cited, in whom the extensive involvement rendered resection or short-circuiting operation unwise, has remained well following discharge from the hospital (six months). The advisability of trying conservative management in selected cases is suggested by the experience which has accrued in the follow-up management of extensive recurrences following resection. Some of these patients remain quite comfortable and well nour-

ished with adequate care in spite of pronounced involvement of the intestine and mesentery. Furthermore, in the preoperative preparation of our patients many were rendered symptom free and afebrile prior to operation as a result of intensive medical management. Quite often the fever subsides, diarrhea is controlled and weight gain is achieved in a relatively short time.

Medical Management.—Adequate medical care of this disease should be thoroughly understood, since it must be carried out prior to any contemplated operation, following all types of surgical procedures and in the treatment of recurrences following operation. Furthermore, in some instances the involvement is so extensive that operative procedures cannot be undertaken.

The features of the disease which often require special therapeutic attention include severe infection, undernutrition, protein deficiency, hypochromic anemia, vitamin deficiencies of all kinds and steatorrhea. Less often calcium deficiency and hepatic dysfunction must be combated. A brief discussion of medical therapy follows:

Diet: A high protein, high carbohydrate diet is indicated. Ample proteins are essential in order to prevent or to overcome a tendency toward protein deficiency. Often the great bulk of calories must be supplied in the form of carbohydrates because of faulty absorption of fats in patients with very extensive involvement. The amount of fat permitted in the diet must depend on the presence or absence of steatorrhea. An excessive excretion of fat in the stools should be prevented, since steatorrhea is usually associated with abdominal distention and discomfort and an increase in the number of bowel movements. The tolerance to ingestion of fiber varies. If the diarrhea is pronounced or partial intestinal obstruction is present the diet should be bland and contain very little cellulose fiber. During the less active phase of the disease many patients tolerate a normal amount of cooked fiber, and in some instances even uncooked fiber is well borne. Just as in ulcerative colitis, sensitivity to certain foods may develop. Intolerance to milk may be noted in some patients during the active phase of the disease and in others with very extensive involvement.

Vitamins: It is essential to reinforce the diet with large amounts of easily absorbed vitamins in order to prevent the occurrence of multiple vitamin deficiency and to maintain good resistance and nutrition. Usually the water soluble vitamins can be given in large doses by mouth. It is doubtful whether complete reliance can be placed on synthetic preparations. Brewers' yeast or some similar natural whole vitamin B preparation has seemed necessary in several of my patients. During that phase of the disease characterized by infection, fever and pronounced diarrhea, water soluble vitamins should be administered parenterally. Very often parenteral water, glucose and salt are required and water soluble vitamins may be added to the intravenous solutions. Vitamin K may be administered intravenously or by injection if the need is great. Adequate amounts of the fat soluble vitamins are usually well borne when administered orally.

The Treatment of Anemia and Protein Deficiency: Severe anemia in regional enteritis is almost always associated with plasma protein deficiency, so that blood transfusions are required until the blood count approximates that of normal. Not infrequently a deficit in plasma protein persists, requiring infusions of blood plasma or amino acid mixtures. It may be very difficult

to maintain a normal plasma albumin concentration in these patients with extensive involvement or continuous fever. In addition to the high protein diet readily utilizable, amino acid mixtures may be required.

In patients with lesser grades of anemia, ferrous sulfate may be administered orally. Injections of crude liver extract may have some value in improving the general status of nutrition.

Calcium deficiencies are occasionally encountered, particularly in those patients who have had an associated steatorrhea. Calcium lactate or gluconate may be given by mouth or parenterally when required.

Ultraviolet Irradiation: Ultraviolet therapy is too often neglected in both regional enteritis and ulcerative colitis. It is difficult to assay its value, but empirically I believe that it has a definite place in the adequately arranged therapeutic regimen for patients who are hospitalized with regional enteritis.

Roentgen Therapy: The use of x-ray therapy has been mentioned by Cutler²⁰ and by Warren and Miller,⁹ but too little experience has been had to warrant an opinion concerning its value. It would be of interest to subject a number of patients with recurrences or with inoperable lesions to x-ray therapy, although it is unlikely that it will prove of much benefit.

Sulfonamides: The sulfonamides have been tried by a number of clinicians in the treatment of this disease. I have utilized sulfadiazine and sulfathiazole with good results in critically ill febrile patients in preparation for operation. The temperature has quickly dropped to normal in some instances. Succinylsulfathiazole is now being used for one week or more during the course of preparation for operation. The drug may be tried for the treatment of recurrences following operation and in the treatment of patients for whom operation is not being contemplated. At least temporary improvement may be anticipated as a result of the use of succinylsulfathiazole in some instances. It is too early to appraise its final effect on the disease.

Penicillin: Penicillin may be tried in much the same way in which succinylsulfathiazole is now being used. However, it is not likely to prove of value in the treatment of lesions of the gastrointestinal tract when administered parenterally as at present. Obviously neither sulfonamides nor penicillin can be expected to influence the irreparable pathologic changes which occur in many instances.

Vaccines and Serums: Vaccines and serums have not been evaluated in a sufficient number of cases to justify an opinion. It is unlikely that they will prove any more successful than in the treatment of chronic ulcerative colitis.

Palliative Treatment: It is rarely necessary to prescribe opiates to control either pain or diarrhea. Usually the more acute symptoms not due to peritoneal irritation or obstruction are controlled by bed rest and the exhibition of antispasmodics with small doses of phenobarbital.

Digestants: If it becomes difficult to maintain normal nutrition because of diarrhea out of proportion to the extent of disease, a gastric analysis should be performed in order to eliminate the possibility of achlorhydria. If achlorhydria is found the administration of dilute hydrochloric acid may reduce the number of stools. If because of extensive resection or recurrence after operation or involvement of a large part of the intestine the loss of protein and fat in the feces is excessive, large doses of pancreatic substance may be given before and after meals.

Prognosis.—It is apparent that with the use of all known methods of therapy chronic regional enteritis is frequently not overcome. The prognosis in any given instance must always remain in doubt, not for one or two years, but for many years. Not infrequently recurrences take place following resection in spite of the removal of every visible evidence of the lesion. It is probable that, with longer and more adequate follow-up studies, one may not anticipate permanent good results in more than 50 per cent of patients treated by resection of the lesion. However, there is some indication that regression of the disease may follow conservative medical management (case J. C.) or short-circuiting operation with exclusion.³ Certainly clinical remissions do occur, and some patients with extensive involvement of many feet of the small intestine enjoy good health for rather long periods of time. For this reason one should maintain an optimistic point of view concerning the outcome and possibility of improvement in every patient. Even though operation is deemed impossible, adequate medical management should be continued indefinitely, as clinical improvement in some patients may be nothing less than remarkable, following a relatively short period of hospitalization and thoroughly adequate management.

INFLAMMATORY LESIONS OF THE SMALL INTESTINE

SURGICAL ASPECTS

HENRY W. CAVE, M.D.

NEW YORK

The surgical approach to inflammatory lesions of the small intestine is predicated on the type of involvement. Basically there are two types: (1) primary involvement, as is seen in cases of regional enteritis, and (2) secondary inflammatory lesions, as not infrequently follow obstruction of the small intestine or mesenteric thrombosis.

Of necessity, this discussion of the surgical aspects of inflammatory lesions of the small intestine will deal principally with regional enteritis which has involved the small bowel alone, and also with inflammation of the terminal ileum which is associated with ulcerative colitis. Mention will be made of 2 instances, from our surgical service, of chronic organizing enteritis, which aptly, I believe, should come under this general topic.

The most interesting of all primary lesions of the jejunum and ileum is the so-called terminal ileitis, regional enteritis or segmental enteritis, as has been so vividly and completely described by Crohn, Ginzburg and Oppenheimer¹ of the Mount Sinai Hospital in New York. Certainly a tribute should be paid to this group of investigators and surgeons of this particular institution for the outstanding work that has been done by them and under their direction in this disease. From time to time complete reports on the various aspects both medical and surgical have emanated from this clinic. Our experiences at the Roosevelt Hospital has

been limited as to numbers, and in that respect are not comparable to the series of the Mount Sinai Hospital.

In all there were 23 cases of regional enteritis in the surgical services of our hospital during the past ten years. Of the 23 patients operated on, 19 were males. Seven were operated on with a preoperative diagnosis of acute appendicitis and, of the 7, five appendectomies were performed. Four had been previously operated on and resections of the terminal ileum and ascending colon carried out. These 4 cases could be called possible recurrences because of the fact that they all recurred near the site of the previous anastomosis. In one, a man of 25, admitted with a fecal fistula, who had previously had a resection of the small bowel and ascending colon, the condition necessitated further excision of the small intestine, to the extent that only approximately 3 feet of small bowel remained. There were 6 instances in our series in which there was an inflammatory involvement at the terminal ileum associated with ulcerative colitis.

All of these necessitated wide resection of the ileum as well as a good portion of the large bowel. One could term this group as right sided ulcerative colitis with terminal ileitis.

Of the 23 patients in this series, 3 died. One was a man of 34 who was admitted to the hospital with a diagnosis of perforated peptic ulcer. At operation a perforation of the ileum was sutured. He was thought too ill to carry out other procedures. Autopsy revealed acute general fibrinopurulent peritonitis and terminal ileitis with perforation. The second patient was a youth of 19 who had had elsewhere a resection of the terminal ileum and an ileosigmoidostomy. Ileocolostomy and partial colectomy were performed. Four months after the second operation an obstruction developed. The ileum perforated and death from peritonitis ensued. The third patient who died was a woman of 22 who had been given an ileostomy and later subtotal colectomy. Two years later she died from a perforation in the terminal ileum which postmortem examination revealed to be a perforation 8 inches from the ileal stoma in a segment of bowel which had all the characteristics of regional enteritis.

It is the early stage of this disease that has so frequently been confused with acute appendicitis, there being pain in the right lower quadrant of the abdomen, direct and rebound tenderness at McBurney's point, fever and leukocytosis. In 4 instances in my own private practice, all before 1938, the diagnosis of acute appendicitis was made and the abdomen opened through a McBurney incision, revealing abundant serosanguinous fluid, the terminal ileum reddened and edematous and the appendix normal. The appendixes in all 4 instances were removed, a questionable practice, the muscle splitting incision was closed through a right rectus incision, and an exploration was carried out showing the extent of the ileitis and especially the inflammatory involvement of the mesentery. No further procedure was done; the abdomen was closed. All in this particular group operated on over five years ago have failed to show any sign or symptom of a recurrence. One questions that many suffering from the acute phase of the disease necessarily go on into the ulcerative phase followed by stenosis and later fistulous formation.

From the surgical aspect the question of recurrences should be discussed. There are instances no doubt in which the disease recurs at or near the site of a previ-

From the Roosevelt Hospital.
Read before the joint meeting of the Section on Surgery, General and Abdominal, and the Section on Gastro-Enterology and Proctology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

ous anastomosis; this means usually that resection has been incomplete and that potentially if not already inflamed bowel wall has been used in performing ileocolostomy. There may exist a segment or segments of the jejunum higher up that could be identified as an early lesion, had a careful search been made at the first operation.

It is generally conceded that the treatment of regional enteritis is surgical. Most surgeons advocate resection of the involved segment or segments either in one or in two stages. If the two stage method is followed the interval between first and second is variable, depending on the improvement of the patient.

In the presence of an internal or external fistulous tract, side tracking maneuvers either of the small bowel to small bowel or of the small bowel to the large bowel add considerably to a safer and a more satisfactory outcome.

Two and one-half years ago Colp, Garlock and Ginzburg² advocated ileocolostomy with exclusion for nonspecific ileitis, suggesting that it "is an indirect and simpler procedure" and "can be carried out with a negligible mortality by the surgeon who only rarely encounters the disease." They reported 40 cases without operative mortality or serious postoperative complications. Two days ago at this meeting of the American Medical Association before the Section on Surgery, General and Abdominal, Drs. Garlock and Crohn³ reported 164 cases followed for a period from two to fourteen years with a low operative mortality of 8.5 per cent. They reemphasize the importance of a single short-circuiting procedure with transection of the terminal ileum and are convinced that their results are better than with primary or secondary resection.

I am of the belief that many can be cured permanently by ileocolostomy with exclusion, especially those operated on in the early stages of the disease; others reaching the stage of ulceration, stenosis and fistulous formation will require further surgery before they are cured.

Certain individuals suffering from ulcerative colitis present involvement of the terminal ileum in varying degrees. We have considered this for the most part a continuation or spread of the disease backward through the ileocecal valve; however, in 7 of the 80 patients on whom we have operated primarily for ulcerative colitis, we found inflammatory lesions of the small intestine resembling regional enteritis.

Tuberculosis of the small intestine, especially at the ileocecal junction, may be a primary lesion; however, generally the lung is the primary seat. These have to be dealt with surgically; formerly it was thought that by merely opening the abdomen or instilling free oxygen into the peritoneal cavity cures were effected. Resection of the involved area has proved valueless unless heliotherapy or medical management will arrest the original focus.

Secondary inflammatory lesions following mechanical intestinal obstruction, volvulus or mesenteric thrombosis have their surgical implications. Infection is succeeded by embarrassment to the blood supply. Perforation with resulting peritonitis can be anticipated unless the gangrenous segment is removed. The Miller-Abbott tube, a valuable adjunct in intestinal surgery,

frequently has been misleading and has given a sense of false security in numbers of instances of acute ileus due to a band or torsion of a loop or loops of small bowel.

There is an unusual chronic inflammatory lesion which involves the entire small intestine which should be mentioned in this discussion. In 1908 Dr. Miles F. Porter and Dr. William H. Welch⁴ reported before the Section on Surgery, General and Abdominal, an unusual pathologic specimen. The specimen revealed the entire small intestine covered with a grayish white, strong membrane, cartilaginous in part, which covered up and closed into a small mass the entire small bowel. The fatality had resulted from intestinal obstruction due to this constricting, encircling membrane. Dr. Welch's pathologic diagnosis was "chronic organizing peritonitis from numerous transverse infoldings or constrictions of the intestinal wall, this being held in place by bridges of dense organizing false membrane."

Dr. Charles N. Dowd⁵ in 1923 reported from the Surgical Division of the Roosevelt Hospital a case in which a man aged 46 complained of pain and a mass in the lower part of the abdomen. He found at operation a lobulated irregular mass measuring 24 cm. in length and 10 cm. wide covered by a thickened membrane, the entire mass giving the appearance of having been the site of an inflammation. "It was found that the tumor was composed of convoluted and adherent small intestine bound into an irregular mass by some peculiar pathological process." An anastomosis was made around this mass between a loop of the jejunum and a segment of the terminal ileum. A leak occurred at the site of anastomosis. The patient died on the thirty-third postoperative day.

In January 1941 a 12 year old girl complaining of recurrent attacks of nausea and vomiting and dull epigastric pains was admitted to the Surgical Service of the Roosevelt Hospital. The child had a tumor in the left upper quadrant of the abdomen. X-ray examination revealed distended loops of jejunum in the left upper quadrant with a 50 per cent six hour gastric residue. At operation a fair sized tumor mass covered with a thick grayish membrane was found in the left upper quadrant. It was difficult to determine whether this mass was in the peritoneal cavity or in the retroperitoneal space. Except for 4 or 5 inches of the terminal ileum, almost the entire intestines were clustered together under this thickened membrane, and the loops were found to be adherent to one another. This thickened membrane, covering almost the entire small intestine like a cap, was dissected off, and the loops of small bowel were straightened out. The patient made an uneventful recovery. A follow-up in March 1944 revealed the abdomen to be entirely normal. Studies of the small intestine revealed nothing unusual.

This condition has been variously termed multiple progressive hyaloserositis and chronic multiple serositis. The etiology is unknown. The mucous membrane of the intestine in this condition becomes puckered into various shapes and various size folds and will completely obliterate the lumen of the bowel. The actual surgical removal of the encasing membrane is the only method of treatment through which recovery can be expected.

SUMMARY

Numerous patients with early acute regional enteritis will recover without resection or even without ileocolostomy with exclusion. Appendectomy in the early stage or other stages invites disaster. In the surgical management of regional enteritis resection in one or two stages has been generally accepted as the procedure of choice. Colp, Garlock and Ginsburg believe that a sufficient number of patients can be cured by ileocolostomy with exclusion alone so that resection is unnecessary. Certainly their results with this procedure have been most encouraging. A certain percentage of patients suffering from ulcerative colitis have an associated ileitis. This diseased terminal ileum should be removed at the time of partial or complete colectomy.

A rare inflammatory lesion of the small intestine termed chronic organized enteritis was recently treated in the Surgical Service of the Roosevelt Hospital.

West Fifty-Ninth Street and Ninth Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. BOCKUS AND CAVE

DR. BERRILL B. CROHN, New York: The duration of illness before surgery was applied for was twenty-seven months. This delay is one of the reasons why, possibly, the surgical results have not been as promising as they should be and are to date disappointing. What happens during those twenty-seven months during which the disease passes without a diagnosis? Dr. Bockus mentions a febrile, an indeterminate protracted form of the disease. One of my first cases of ileitis was reported in the *New England Journal of Medicine* as a case of brucellosis with unusual manifestations of small intestine involvement, a case with continuous fever, in which the ileitis was not identified. More and more cases in which there is fever for months are diagnosed by competent medical men as rheumatic fever, periarteritis nodosa, Libman-Sachs disease or subacute bacterial endocarditis; often the diarrhea is not noted for many months. Once the clinical phenomenon of diarrhea has announced itself, the diagnosis of ileitis or of segmental colitis accounts for all the previous symptoms. There is apparently a long lag between the beginning of symptoms and the eventual diagnosis of inflammatory intestinal disease with recourse to surgery. The better results that can be shown and will be shown in the future with the surgical treatment of this disease will depend in great part on earlier diagnosis. Dr. Garlock and I reported a large group of cases of ileitis (65 cases) in which the surgical attack was ileotransverse colostomy with transection of the ileum; the mortality in this series was nil. In our experience the incidence of recurrences was 10 per cent. That is much better than has been shown by us in the past. The future will depend on the factors, namely the responsibility of the medical men for an earlier diagnosis during those twenty-seven months, and the ability of the surgeons to determine just what is the best and simplest surgical procedure, one with the least mortality and with the highest percentage of promising returns.

DR. MARIE ORTMAYER, Chicago: A woman aged 52 had been ill for nine months with what had been diagnosed duodenal ulcer and anemia. In the month before I saw her she had lost 20 pounds (9 Kg.). She complained of mild epigastric pain, not exactly related to eating, of vomiting with some relief from the pain, and of diarrhea of recent onset. Her previous history was negative except for pneumonia ten years before. She weighed 72 pounds (33 Kg.). Her temperature fluctuated daily from normal to 100, 101, and occasionally 102 F. Her pulse rate was above 100, her respiratory rate 20. Her lungs and heart were normal with a functional systolic murmur. Her fingers were clubbed and her tongue at times was beefy red. The blood protein was normal in range and ratio; the red blood cell count was 3,680,000; the white blood cell count was 10,300; hemoglobin was 68, polymorphonuclears were 72 per cent, the Kahn reaction was negative. The stools were pasty and light colored. Of 27, 19 showed traces to 4 + reactions to benzydine. On 3, formaldehyde digestion tests for acid fast bacilli showed none. There were no amebas, cysts or ova. Dysentery and

typhoid cultures were negative. Roentgenologically the stomach was normal. The duodenal cap showed a deformity consistent with duodenal ulcer but no crater. The small bowel study with 2 ounces of barium and water each was of real aid in the diagnosis. The roentgenologist diagnosed multiple partially obstructing strictures of the jejunum with possible ulceration at two points. Surgery was declined because of the obvious risk and widespread lesion. Three days before death the patient developed sudden severe abdominal pain and tenderness, suggesting peritonitis. Autopsy confirmed the latter. The gross specimen of the jejunum showed healed constrictions. There was a transverse ulcer with a perforation. In the microscopic picture all was necrotic. There were no tubercles. It was not at all like terminal ileitis but rather a necrotizing, constricting, perforating, multiple ulcerative jejunitis of unknown origin.

DR. HENRY W. CAVE, New York: There is a new drug, a sulfonamide drug, which has been most helpful in our surgery, called sulfathalidine. I have used it in 58 instances simply in the preoperative preparation of patients for small and large bowel intestinal surgery. The drug has three merits. It is more potent than succinylsulfathiazole, it is absolutely nontoxic, and it can be given in smaller doses than sulfaguanidine or succinylsulfathiazole. We have recently given it to patients suffering from ulcerative colitis, and there has been no amazing change in the few patients treated. We have not used it long enough to give any kind of authoritative report on it, but certainly in preparing patients for ileostomy or for subtotal colectomy and for cancer of the colon, who are not in good shape and have ulcerative colitis in an extensive form this drug has been helpful.

Clinical Notes, Suggestions and New Instruments

ARTIFICIAL INSEMINATION AS A MEANS OF PREVENTING ERYTHROBLASTOSIS

EDITH L. POTTER, M.D., AND J. ROBERT WILLSON, M.D.
CHICAGO

The theory of maternal immunization to the Rh factor as the primary etiologic agent in the production of erythroblastosis has become widely accepted in the last few years. Clinical observations are in remarkably close agreement with the findings which are to be expected on the basis of the theory, and although part of the actual mechanism by which the disease is produced is still unknown the basic facts must be considered as established. The following conditions should exist if the theory is correct:

1. The mother is Rh negative.
2. The father is Rh positive.
3. The fetus is Rh positive, the Rh positive gene being inherited as a mendelian dominant.
4. The Rh factor passes from the fetus to the mother. The mode of transmission has not been proved but is presumed to be by passage of Rh positive fetal erythrocytes from the fetal to the maternal circulation.
5. Anti-Rh agglutinins are produced in the maternal organism.
6. Anti-Rh agglutinins pass from mother to fetus.
7. An antigen-antibody response occurs in the fetus.

All of these conditions are in agreement with clinical observations. Almost all of the mothers who have been tested are Rh negative, and in the few instances in which erythroblastosis has been reputedly found in the infants of Rh positive women the disease may have been due to immunization by some other antigen, or there may have been an error in performing the test or in the diagnosis of erythroblastosis. Almost without exception the fathers and the affected infants have been Rh positive. Agglutinins have been demonstrated in a high percentage of adequately studied mothers; moreover, inability to demonstrate agglutinins in vitro does not necessarily indicate physiologic absence. The pathologic lesions which characterize erythroblastosis are abnormal destruction and production of

From the Department of Obstetrics and Gynecology, the University of Chicago and the Chicago Lying-in Hospital.

erythrocytes. The destruction is best explained as an antigen-antibody reaction and the abnormality in blood formation as secondary to the blood destruction.

Three further clinical observations which must be explainable by this theory if it is correct are (1) the development of the disease in the offspring of only a small proportion of women who are Rh negative, (2) the rare occurrence in a first pregnancy and (3) the almost constant repetition in pregnancies subsequent to one in which an infant develops erythroblastosis.

The fact that erythroblastosis ordinarily has an incidence of only one in every three or four hundred births, while in a random population approximately one in eleven pregnant women is Rh negative and is carrying an Rh positive child, indicates that some additional element must be present before erythroblastosis will develop, even though the Rh distribution would permit its occurrence. The most probable inciting factor is an abnormality of the placenta which permits fetal erythrocytes to escape into the maternal circulation. It might be suggested that fetal cells enter the maternal blood in all pregnancies and that those Rh negative women who give birth to normal infants are incapable of forming antibodies. It is unlikely, however, that no more than 3 per cent of Rh negative women are capable of such response, and future investigations may disclose some heretofore unsuspected precipitating agent.

Erythroblastosis is rarely found in a first born infant unless the mother has had a previous abortion or blood transfusion. When it does occur in a first pregnancy the disease is usually mild; in the series of over 100 infants with erythroblastosis observed at the Chicago Lying-in Hospital there have been no fatal cases among those born to untransfused primigravid women. If maternal immunization could be produced during the course of a single pregnancy and a sufficient concentration of antibodies attained to cause a typical immune response in the fetus, there would seem to be no reason why erythroblastosis should not occur with the same frequency in primigravid as in multigravid women.

Furthermore, if the immunity was initiated by and the manifestations were limited to a single pregnancy it seems most improbable, not only that first born infants would escape, but that a pathologic lesion identical to that first producing the disease, such as a break in placental vessels, would exist in all succeeding pregnancies.

The fact that almost all women bear one or more unaffected children before giving birth to an infant with erythroblastosis and that practically all infants born subsequently are affected with the disease seems definite evidence that the immunity is ordinarily established in the pregnancy preceding the first in which erythroblastosis is evident and that once produced it is either permanent or is further stimulated by some condition inherent in all pregnancies.

On the basis of the foregoing conclusions it appears that the only infants who should escape the disease after the mother has once become immune are those who do not possess the Rh antigen necessary to complete the antigen-antibody reaction, i. e. those who are Rh negative. The three Rh negative children observed at the Chicago Lying-in Hospital whose older siblings died of erythroblastosis have all been normal. All Rh positive children born subsequent to an infant with erythroblastosis have had the disease.

The first such Rh negative infant was the child of a woman who had had six previous pregnancies: a normal female in 1931, abortion at eight weeks in 1933, abortion at six weeks in 1936, remarriage followed by a normal female in 1937, a normal male in 1939 and a stillborn infant with typical erythroblastosis in 1942. Anti-Rh agglutinins were present in this woman's blood two months after the delivery in 1942. In 1943 a normal infant was born in spite of the fact that anti-Rh agglutinins were present in the maternal circulation at that time. This last child is Rh negative, the mother is Rh negative and the second husband is Rh positive.

The second Rh negative infant was one of twins and has been previously reported.¹ The mother was Rh negative, the father Rh positive; one twin who was Rh positive died of erythro-

blastosis, while the twin who was Rh negative was unaffected. No anti-Rh agglutinins were demonstrable at any time. The mother had had one previous pregnancy ending in the delivery of a normal child, who was 9 years of age at the time the twins were born. This case indicates that an Rh negative infant will escape the disease in an environment that is capable of producing it in an infant who is Rh positive.

The third infant is the most important and is the one with whom this paper is primarily concerned. We have observed previously that, as would be expected, a woman who has had an infant with erythroblastosis by one husband will have infants with the same disease by another Rh positive husband. We believe, however, that if she becomes pregnant by sperm from an Rh negative man she may be assured a normal child. Artificial insemination by sperm from an Rh negative donor would seem, therefore, a means by which a woman who has been immunized to the Rh factor could give birth to a normal infant.

Mrs. A at the age of 31 delivered a female child who was normal at birth and who is now alive and well and of blood group O Rh+. Three years later she had a spontaneous abortion. The following year she again became pregnant and gave birth to female twins both of whom exhibited clinical evidence of erythroblastosis. Both died, and the diagnosis was confirmed at postmortem examination. The blood of the patient was found to be A Rh—, the husband O Rh+. The twins were not tested. In view of the existence of typical erythroblastosis in these offspring it was considered unwise for her to attempt further pregnancies except by insemination with semen from an Rh negative man. Approximately one year later the patient was artificially inseminated on the fourteenth and sixteenth days of one menstrual cycle and on the thirteenth and fifteenth days of the following cycle. She did not conceive and two months later was inseminated on the eleventh and sixteenth days with sperm from another donor. Two hundred and sixty-eight days after the last insemination she gave birth to a normal female infant whose blood is A Rh—. The infant is now 2 months of age and has had no symptoms of erythroblastosis.

The fact that a woman may give birth to a succession of infants with erythroblastosis by one man and will continue to have children with the same disease by another Rh positive man, and that a woman who has had infants with erythroblastosis will have a normal child if impregnated with sperm from an Rh negative individual, seems further definite proof that fetal response to maternal immunity produced by the Rh factor is the fundamental cause of erythroblastosis.

SUMMARY

Further evidence to support the theory of maternal immunization to the Rh factor as a cause of erythroblastosis lies in the fact that an Rh negative woman who had given birth to infants with erythroblastosis was successfully impregnated by artificial insemination with Rh negative sperm and gave birth to a normal Rh negative infant.

HAZARDS IN THE SALICYLATE TREATMENT OF RHEUMATIC FEVER

Dangers encountered in the administration of large amounts of salicylates recently have been reported. Salicylates have long been used in the treatment of rheumatic fever. Physicians are familiar with the astonishing relief the drug gives the stricken child. Acutely inflamed joints that are so sensitive that they cannot tolerate the weight of the bedclothes soon are able to resume their normal function after the administration of salicylates. The antipyretic properties of the drug are as striking as are the analgesic effects.

Recently Coburn¹ advocated the administration of large doses of salicylates in acute rheumatic fever. He recommended the intravenous administration of 10 Gm. of sodium salicylate in 1,000 cc. of 0.9 per cent sodium chloride every day for four days. Intravenous medication was given slowly over a period of four to six hours, so that sufficiently high concentrations of the drug in the body could be reached and maintained. Plasma salicylate values of 400 micrograms per cubic centimeter could be attained by his method. In fact, Coburn believed that values of 150 to 200 micrograms, easily attained by oral administration of salicylates, while providing relief from the acute symptoms of rheumatic fever, failed to halt the progress of the disease. He contended that serum salicylate values of 350 micrograms per cubic centimeter or more must be maintained if the "rheumatic reaction" was to be held in check. Protocols of his small series of cases furnished some remarkable results, especially the rapid resolution of the acute phases of the disease, as judged by the quick return of sedimentation rates to normal and the sudden disappearance of clinical signs. Many are not in accord, however, with his thesis of the early curtailment of the damage inflicted by the "rheumatic reaction." It has been pointed out that sufficient time has not elapsed to judge fairly the results of Coburn's treatment. This is particularly true in regard to the incidence of mitral heart disease, pericarditis and pancarditis, common aftermaths of acute rheumatic fever.

Large amounts of salicylates cannot be given without careful clinical observation of the patient. Death and severe complications from salicylates have been recorded.² Patients should be questioned concerning any sensitivity to salicylates before the drug is given. The appearance of tinnitus, vertigo, deafness, nausea or other symptoms should indicate the cessation of further administration of the drug. Hypoprothrombinemia has been reported to follow salicylate therapy;³ some have found that adequate amounts of vitamin K⁴ will protect against this contingency.

The whole problem of salicylate intoxication was recently studied by Fashena and Walker⁵ after their attention had been drawn to the subject by the observation of a patient with salicylate poisoning. They studied 6 children, to whom they gave large amounts of sodium salicylate by mouth every four hours. Blood salicylate levels of 350 micrograms per cubic centimeter were maintained throughout the study. Prolongation of prothrombin time was found in every instance.

Rheumatic fever often is accompanied by a widespread vascular damage, thus increasing the hazard of hemorrhagic complications after salicylate administration. When adequate amounts of vitamin K are given with salicylates, much of the danger of these complications may be prevented. Possible hazards in the administration of salicylates should be remembered so that unnecessary dangers may be avoided.

SENESCENCE, SENILITY AND CRIME

The relation between age and crime is significant socially. East¹ emphasizes that most magistrates are not appointed until they have reached middle age; the preponderance of middle age and elderly judges, he feels, may be far from desirable in cases involving juvenile crime. East quotes a circular in 1936 which declared that, "apart from the obvious advantage attaching to quickness of hearing and of sight in justice, there is the fact that as time goes on men and women justices are apt to lose the freshness of mind and sympathy and the up to date knowledge of social conditions which are of extreme importance for successful work in the juvenile courts." The particular problems of the aged or senile person who commits a crime deserve special study. Although this report cites British figures and British problems, there is ample reason to believe that the situation in the United States

is in most respects parallel. The trial of aged persons by their contemporaries may be unsatisfactory, East says. Age itself is not necessarily a true measure of senescence, using that word for the normal process of growing old, or of senility, used in a sense of abnormal mental states which sometimes supervene toward the close of life. Consequently special attention should be given to the manner of thought and behavior of the aged. The onset of normal old age, or senescence, is a physiologic condition rather than a pathologic state, and is therefore difficult to determine its onset. The chronologic age is often misleading as an index of the onset of this physiologic process: authorities have placed it in the early forties, at 55, at 65 and probably at many other ages. Most modern students are inclined to agree with the late Sir Humphry Rolleston that in healthy persons the onset of senescence is so stealthy that it is seldom suspected by the person himself. One man may be senile at 60 while another is vigorous in both mind and body at 80. In criminology the important feature of normal senescence is the degree of control exerted by the will when directed toward the discouragement of illegal acts which would put the interests of the individual ahead of those of society in general. East adds to this the action of the will in encouraging activities which are legal and useful to society, however strongly they may be opposed to the desires of the participant. When the hitherto blameless senescent becomes involved in illegal behavior as a result of mental deterioration, he deserves, East says, the fullest understanding from those who judge him, and this requires insight into the background of his mental life.

Normal aging passes into senility when the impairment of intellectual, emotional and volitional attributes of mind becomes excessive and the mental activities are imperfectly synchronized with resultant inability to form well considered opinions, to exert sustained effort and when social maladjustment results. The reason senility develops in some persons and not in others appears to depend, at least in part, on the inherent constitutional makeup and the degree of cerebral arteriosclerosis present, on the stresses which they have experienced and indirectly on the manner of life. Used in this sense, the term senility would be restricted to senile and arteriosclerotic dementias. Although aged prisoners are generally treated under a milder form of discipline than others, the mental background of the offender before trial is also important but has received less attention than is due it. In matters involving criminal responsibility in the aged, East says attention must be paid not only to the standards of so-called normal persons but also to the conduct and mental condition of the senile offender during his younger years. Where mental abilities are superior during the prime of life, it is especially easy to overlook perceptible degrees of deterioration due to age because the offender is com-

pared with those of merely average intelligence and ability of comparable years.

Out of a group of 9,197 prisoners of both sexes in the prisons of England and Wales recently convicted for various offenses, 290 were aged 60 years or over. Of these, 71 were first offenders and 194 had been previously convicted three times or more. The number and proportion of aged persons in the population is constantly increasing. Although the incidence of crime among the aged and senile will doubtless vary in response to hereditary, social and economic factors as well as to age, the problem will doubtless increase more or less consistently. Close working contact between physicians familiar with the mental problems of aging and of the courts is highly desirable in order that the cause of justice may be best served for those criminals of older years whose actions are affected by senescence or senility.

PARAGONIMIASIS IN RETURNING WAR VETERANS

When patients complain of chronic cough, pain in the chest and bloody sputum the physician today considers tuberculosis, lung tumor and bronchiectasis in the differential diagnosis, with lesser consideration to blastomycosis and other diseases. To these, in the case of men who have been in the tropics and particularly the Asiatic-Pacific theater, paragonimiasis, or endemic hemoptysis, caused by infection with the lung fluke *Paragonimus westermani*, must now be added.

Miller and Wilbur¹ have recently reported 3 cases in Marines and have seen 4 others. Numerous additional cases will no doubt be reported as the disease increases and as it is recognized. Paragonimiasis is contracted by eating raw or inadequately cooked crabs or crayfish. The encysted metacercariae (larval worms) so ingested burrow through the jejunum into the peritoneal cavity; then they migrate to the lungs and sometimes to other parts of the body. Small nodular granulomatous lesions are formed about the flukes in the walls of the smaller bronchi. The adult worms pass ova, which are eliminated with the sputum or feces.

The symptoms are caused by the presence of the worms or their ova in the various tissues of the body, particularly the lungs and blood vessels, or by secondary infection. The agents act as mild irritants, inducing a chronic inflammatory reaction and leading to tubercle-like lesions or to thrombosis. Despite these changes the physical and x-ray findings may be absent or minimal. They may be those of a chronic bronchitis or bronchiectasis. Eosinophilia is not a constant accompaniment. The diagnosis is made by demonstrating the characteristic ova in the sputum or, less

1. Miller, John J., and Wilbur, Dwight L.: Paragonimiasis (Endemic Hemoptysis), U. S. Nav. M. Bull. 42: 108 (Jan.) 1944.

commonly, in the feces. Depending on the number and predominant location of the worms and their ova elsewhere in the body, extrapulmonary forms of the disease have been described. These include abdominal, cerebral and lymphoglandular forms. Specific treatment is not now available.

The chain of infection is precarious because two intermediate hosts are required in addition to the definitive host. The ova are passed from the definitive host, which is man or some other mammal. The larvae, which develop from the ova, enter a specific species of snail. After further development the larvae enter a crab or a crayfish, from which man may be infected.

Although the life cycle of these lung flukes is complex, the possibility exists that the infection can be established in this country. The cases need to be recognized as early as possible so that careful disposal can be made of the sputum. While this disease does not yet rank in importance with filariasis and malaria as a problem in veterans returning from the Pacific theater, its incidence will probably increase as our troops enter the areas in which the disease is more prevalent. Because of the insidious onset and the chronic course the disease may sometimes make its first clinical appearance after the men have left military service. In cases of obscure disease of the chest in veterans the civilian physician should consider the diagnosis of paragonimiasis.

Current Comment

THERAPY OF ALCOHOL ADDICTION

The treatment of chronic inebriety today often includes services by the lay therapist, who participates in the rehabilitation of the chronic alcoholic addict. The qualifications of the lay therapist have become more important because many of those who have recovered from alcoholism desire to help in the rehabilitation of those who are still addicted. The therapy of alcoholism is complex; agreement has not yet been reached as to the preferred method or methods of procedure. A recently published symposium¹ on this subject views the problem in its various aspects. The prevention of inebriety is considered by Abraham Myerson, who suggests that the prevailing social attitudes toward the chronic drinker must be altered through education and social propaganda. The aversion method recognized as an application of the conditioned reflex is the subject of an important critique by Professor Carlson. The theory of the allergic nature of alcohol addiction is analyzed and dismissed by Dr. Haggard. An attempt is made to establish an alcoholic personality. Other papers in the symposium include discussions of the relation between the alcoholic patient and the physician, the contribution of the minister to the treatment of the alcoholic addict and the therapeutic role of Alco-

holics Anonymous from the point of view of a sociologist. The physician, the sociologist, the judge, the minister and the psychologist will all find this symposium the source of invaluable information in their dealings with the important and growing problem of the chronic inebriate.

SOME FACTS ABOUT TSUTSU- GAMUSHI DISEASE

Recent studies indicate that typhus-like fevers in Asiatic and Australasian regions are closely related to if not identical with the Japanese tsutsugamushi disease. Farner and Katsampes¹ have made a comprehensive and timely review of the history, nature and etiology, distribution, variations and nomenclature of the disease. Tsutsugamushi is "the Japanese pronunciation of two Chinese idiographs meaning small creature, which, according to early Chinese literature, caused disease by boring into the human body."¹ Japanese investigators showed that the disease is transmitted by the bite of chiggers (larval trombiculid mites), which causes a characteristic lesion of the skin. The typhus-like infections included by Farner and Katsampes under tsutsugamushi disease appear to be caused by mite borne rickettsias. Rickettsia tsutsugamushi is the accepted name for the Japanese strain; its relationship to other strains is under study. The reservoirs or natural hosts of these rickettsias are animals, particularly rats, field mice, possibly certain birds, and the field vole. Damp ground covered by dense grass and shrubbery undoubtedly favors the development of the larval mites. Farner and Katsampes conclude that "provisionally it seems best to assume that tsutsugamushi disease is primarily a widespread disease of several (or many) species of vertebrate animals in Asia and Australasia, transmitted by certain trombiculid larvae and contracted accidentally by humans in contact with habitats containing the mite larvae." As shown by recent reports, the infection is of immediate concern in the Pacific warfare² and has been found to occur in places where it was unknown or unsuspected. The wide spread of mite borne rickettsiosis, variations in the factors concerned and in clinical manifestations, and the unavoidable lack of close cooperation on the part of early investigators have led to great confusion in the terminology of the disease. Farner and Katsampes list some fifty-five names used in writings about the fevers now included under tsutsugamushi disease. Of these names rural, tropical or scrub typhus, typhus group, Mossman fever and tsutsugamushi disease have been used by English writers. The establishment of the etiology of this disease or group of related diseases has brought with it effective methods of prevention. Personal protection consists in the avoidance of bites by mites. The epidemic described by Logue² was controlled by thorough cleaning of camp sites of grass, shrubbery and rubbish, destruction of rodents, and individual protection, including the thorough application of dimethyl phthalate.

MEDICINE AND THE WAR

ARMY

ARMY RECONDITIONING BASED ON INDIVIDUAL NEEDS

More than 100,000 sick and wounded are now participating in the Army's reconditioning program, in which emphasis is focused on the individual soldier's own interests, his likes or dislikes, talents and background. Mass regimentation is out. Col. Augustus Thorndike is in charge of the reconditioning Division of the Office of the Surgeon General, which was created in July 1943. It is his belief that reconditioning is a new technic in modern military medicine.

The reconditioning program is divided into three broad general phases: physical reconditioning, educational reconditioning and occupational therapy. The physical reconditioning phase embraces a scientifically planned schedule of activities, including remedial exercises, bed calisthenics, sports and games, gymnastics, combatives, guerrilla exercises, marching and running. All are designed to retard bodily deterioration during the early stages of convalescence and later to restore the strength, endurance and coordination which go into the makeup of an efficiently performing soldier. Educational reconditioning is intended to augment the medical and surgical cures or repairs with a varied list of subjects which will stimulate the minds of men compelled to lie for weeks or months in a hospital bed, to forestall the mental depression setting in with idleness. Occupational therapy, like the bed exercises and educational activities, starts as soon as the patient is physically able. The mild exercise and mental relaxation of constructive work by bedridden patients has been found to speed up their recovery beyond the rate accomplished by medical care.

Through the efficient functioning of the Medical Division, the Preventive Medical Service and other branches of the Army Medical Department, the Army has reduced the death rate from disease to a figure that is lower than that for any of the ten peacetime years preceding our entrance into the war. The Surgical Service has established a new record in military history by saving the lives of 97 per cent out of every hundred wounded men who reach a hospital alive.

In the same way this latest undertaking of the Medical Department, the Reconditioning Division, has reached the point where 12,000 officers and enlisted patients are returned to active duty every week.

PLAN TO INCREASE BED CAPACITY OF ARMY HOSPITALS

Major Gen. George F. Lull, deputy surgeon general, recently announced that plans are nearing completion to increase the bed capacity of the Army's general and convalescent hospital system by 70,000 to care for the additional sick and wounded soldiers returned from overseas. At present the rate of evacuation of casualties to this country is more than 30,000 each month, as compared with the first six months of 1944, when the total was approximately 9,000 a month. One means of providing the additional facilities has been the temporary conversion of four station hospitals to the general and convalescent type. They will be known as U. S. Army general hospitals but not as name general hospitals. These are located at Camp Edwards, Falmouth, Mass.; Camp Pickett, Blackstone, Va.; Camp Butner, Durham, N. C., and Camp Carson, Colorado Springs, Colo.

Another feature of the program will be the expansion of some convalescent hospitals in several of the service commands. After a soldier has been treated at the general hospital which specializes in his particular type of injury, the Army will transfer him to a convalescent hospital. There reconditioning treatment speeds his recovery. This procedure also makes available more general hospital beds for the more serious cases. In

addition to the four named, the list of expanded installations includes Camp Upton Convalescent Hospital, Yaphank, L. I., N. Y.; Fort Story Convalescent Hospital, Virginia Beach, Va.; Welch Convalescent Hospital, Daytona Beach, Fla.; Wakeman General and Convalescent Hospital, Camp Atterbury, Ind.; Percy Jones General and Convalescent Hospital, Battle Creek, Mich.; Mitchell Convalescent Hospital, Campo, Calif., and Old Farms Convalescent Hospital, Avon, Conn.

MAJOR GENERAL HAWLEY PAYS TRIBUTE TO ARMY NURSE CORPS

Major Gen. Paul Hawley, chief surgeon of the European theater of operations, recently paid high tribute to the Army Nurse Corps on its forty-fourth anniversary, stating that "one of the most glorious pages in the history of the Army Nurse Corps is being written today. . . . Magnificent is the one word that describes the job they are doing."

In commenting on the serious shortage of nurses which exists not only in hospitals overseas but at installations within the United States as well, General Hawley pointed out that the critical lack of nurse reinforcements has forced the Medical Department three times to reduce the number of nurses stationed with each hospital. In 1940 there were 120 nurses to a 1,000-bed army general hospital; in 1943 the number was cut to 105 and in 1944 to 83. At the same time the bed capacity of many hospitals has been increased, with 1,000 bed hospitals carrying an average load of 1,300 patients each. Nurses who have been overseas for more than two years are working twelve, often as long as sixteen, hours a day. "The army nurse is a good soldier; she asks no favors. But she is becoming tired. There is only one solution: we must have more nurses," General Hawley stated.

SUDDEN TOOTHACHE DURING HIGH ALTITUDE FLYING

Sudden toothache occurring during high altitude flying is a serious personnel problem for the Army Air Forces, according to a recent article by Drs. Balint Orban and Beryl T. Richey in the *Journal of the American Dental Association*. Two out of every hundred cadets and officers given altitude training may experience such severe pain that their only thought is of immediate and rapid descent. They found that recently placed fillings in deep cavities are most likely to cause trouble. A diseased tooth which might not cause pain on the ground for a period of years was affected by a drop in the barometric pressure. Low temperature in high altitude flying is a negligible factor in pain. The article states that "pain during ascent indicates a tooth with a vital pulp, pain during descent a tooth with nonvital pulp; the sooner the pain starts during ascent the more acute the inflammation in the tooth is apt to be."

UNIVERSITY OF ILLINOIS EVACUATION HOSPITAL IN GERMANY

The University of Illinois Evacuation Hospital (the 27th) is now stationed with the Seventh Army in Germany. Moved from a camp in Kentucky to Africa, then to Italy, then southern France and on north, the unit moved up close behind the battle lines of the Seventh Army onto German soil. It has won three battle stars for service in three countries. The hospital is a 750 bed unit whose total personnel, including patients, ranges between 1,300 and 2,000. The hospital unit is staffed largely by faculty men and alumni of the university's colleges in Chicago.

ARMY AWARDS AND COMMENDATIONS

Major Morris Grayson

The Bronze Star was recently awarded to Major Morris Grayson, formerly of Long Island, N. Y., for his work on malaria control at the base of his unit during the spring and summer of 1944. Situated in a highly malarial district, it was estimated by medical officers that a malarial rate of a minimum of 40 per cent of the group's personnel would result at the unit's base unless the prevailing conditions in the area could be remedied. Major Grayson volunteered to supervise the task of completing a comprehensive preventive program of draining swamplands, clearing vegetation, spraying stagnant waters and educating the group's personnel on individual methods of combating malaria. This preventive work was accomplished so successfully over an area of 16 square miles that less than 1 per cent of the group's personnel contracted malaria during 1943. The citation accompanying the award states that, "after volunteering to take charge of the malaria control program, he entered into every phase of the task and by his example kept his men at a peak of efficiency. Through his devotion to duty, unflinching efforts in the face of all difficulties and outstanding efficiency, Major Grayson has thus reflected great credit on himself and on the armed forces of the United States of America." Dr. Grayson graduated from the University of Lausanne Medical School, Switzerland, in 1937 and entered the service in November 1938.

Colonel Karl R. Lundeborg

The Legion of Merit was recently awarded to Col. Karl R. Lundeborg, formerly of Washington, D. C., for "service from January 1941 to November 1944 in initiating and supervising the development of new methods for the improved control of communicable diseases in the Army, with particular reference to the development of the present program for vaccination against infectious diseases and to the general control of infectious diseases among troops. To these developments in preventive medicine in the Army he has contributed original ideas and direction. A tireless worker with a great fund of knowledge and experience, he has been responsible for many of the important advances in modern military preventive medicine." Dr. Lundeborg graduated from the University of Minnesota Medical School, Minneapolis, in 1926 and entered the service Feb. 24, 1930.

Major Paul Ehrlich Kaunitz

The Bronze Star was recently awarded to Major Paul E. Kaunitz, formerly of New York, for "meritorious service in connection with military operations against the enemy as S-3, 68th Medical Group, from Dec. 10, 1943 to Sept. 21, 1944 in England, France and Belgium. Prior to D day Major Kaunitz demonstrated unusual "ability in training the personnel and integrating the functions of his group's various units into a highly efficient organization. During operations on the continent Major Kaunitz ably coordinated and controlled an effective evacuation system which transported thousands of battle casualties out of battle areas to medical installations." Dr. Kaunitz graduated from New York University College of Medicine, New York, in 1938 and entered the service May 1, 1941.

Captain Maurice S. Raben

The Soldier's Medal was recently awarded to Capt. Maurice S. Raben, formerly of Port Chester, N. Y. The citation read that "at Harvard Army Airfield, Harvard, Neb., on Oct. 24, 1944 an army airplane crashed and burst into flames and its practice bombs exploded. With complete disregard for his own safety he twice entered a compartment of the burning aircraft, searching for members of the crew thought to be trapped in the wreckage. In the performance of these acts he sustained first degree burns." Dr. Raben graduated from New York University College of Medicine, New York, in 1941 and entered the service Oct. 14, 1942.

Captain Frank R. Hill

Capt. Frank R. Hill, formerly of Cleveland, was the recent recipient of the Bronze Star "for meritorious service in connection with military operations against the enemy as neurosurgeon, 45th Evacuation Hospital, semimobile, from June 17,

1944 to Aug. 1, 1944 in France. Captain Hill performed numerous skillful operations on wounded soldiers, often working for twenty-four hour periods without rest or relief, thereby saving the lives of many American soldiers. The surgical judgment and operative technic displayed by Captain Hill were of the highest order and reflect credit on himself and the military service." Dr. Hill graduated from New York University College of Medicine, New York, in 1931 and entered the service Sept. 12, 1942.

Colonel Alfonso M. Libasci

Col. Alfonso M. Libasci, formerly of Brooklyn, was recently awarded the Bronze Star for "meritorious service in planning medical activities in support of the first Philippine operation." Dr. Libasci has also been awarded the Legion of Merit (THE JOURNAL, Sept. 16, 1944, p. 176). He graduated from Long Island College of Medicine, Brooklyn, in 1931, was commissioned as a first lieutenant in the medical reserve corps in 1933 and was transferred to the regular army in 1934.

Captain Frank J. Lavieri

Capt. Frank J. Lavieri, formerly of Chicago, was recently awarded the Bronze Star for meritorious achievement in action in Normandy with a paratroop unit, and the Presidential Unit Citation, awarded to all members of his paratroop group among the first to land in Normandy on D day. Dr. Lavieri graduated from the University of Illinois College of Medicine, Chicago, in 1930 and entered the service Oct. 31, 1942.

Lieutenant Colonel James E. Jobes

Lieut. Col. James E. Jobes, formerly of Indianapolis, was recently awarded the Bronze Star for his services as surgeon in the European theater of operations. Major Gen. Paul J. Hawley, chief surgeon of the European theater of operation made the presentation. Dr. Jobes graduated from Indiana University School of Medicine, Indianapolis, in 1929 and entered the service Jan. 17, 1941.

Major Merrill Moore

Major Merrill Moore, formerly of Squantum, Tenn., was recently awarded the Bronze Star by Major Gen. O. W. Griswold, commanding general of the 14th Army Corps, "for meritorious achievement in connection with military operation against the enemy in the Southwest Pacific." Dr. Moore graduated from Vanderbilt University School of Medicine, Nashville, in 1928 and entered the service May 22, 1942.

Captain Sidney Hershel Mirbach

Capt. Sidney H. Mirbach, formerly of Bethlehem, Pa., was recently awarded the Bronze Star for "distinctive service in connection with military operations against the enemy from July 25 to July 30, 1944." Dr. Mirbach graduated from Jefferson Medical College of Philadelphia in 1937 and entered the service in November 1943.

Captain Harold J. Stoen

Capt. Harold J. Stoen, formerly of Lafayette, Ind., was recently commended by the commanding general of the 13th A. A. F. for his "courageous actions" during an attack by Japanese bombers, when "without thought of self" he left his place of shelter to aid his men. Dr. Stoen graduated from Rush Medical College, Chicago, in 1936 and entered the service in July 1942.

Captain Robert V. Carter

The Air Medal with two oak leaf clusters, Presidential Unit Citation, and Croix de Guerre with palm were recently awarded to Capt. Robert C. Carter, formerly of Tarzana, Calif. Dr. Carter graduated from the University of Illinois College of Medicine, Chicago, in 1936 and entered the service Oct. 15, 1942.

Captain Joseph A. Kurcz

The Bronze Star was recently awarded to Capt. Joseph A. Kurcz, formerly of Detroit, for outstanding service in Belgium. Dr. Kurcz graduated from the University of Michigan Medical School, Ann Arbor, in 1929 and entered the service Nov. 6, 1942.

NAVY

NONMEDICAL VENEREAL DISEASE
CONTROL OFFICERS

The Navy Department recently announced the plans for immediate procurement of fifty nonmedical venereal disease control officers. Candidates for commissions will be considered from civilian life as well as from the ranks of officers and enlisted men. Under Special Program No. 166 of the Bureau of Naval Personnel, these officers will be assigned to various naval activities to conduct educational programs in venereal disease control under the direction of the activity's medical officer. These men will act as liaison officers with civilian health authorities in the area to which they are assigned, establish community relations, lecture on the causes of venereal diseases and how to avoid them, assisted by such visual aids as motion pictures and slides, and keep statistical records on venereal disease control work in their respective districts. They will not administer actual treatment.

Male civilians up to the age of 45 years who are interested and feel qualified for this work may apply at their nearest office of naval officer procurement. If accepted, they will be commissioned in a rank comparable with age, with the maximum rank of lieutenant.

Qualifications are as follows:

1. Applicants should possess the general qualifications for officers as outlined in the Officer Qualifications Manual, and in addition one of the following:

(a) A college degree in any of the basic sciences, public health administration, health education, sociology, psychology or related fields, and at least one year of practical experience in venereal disease control with the U. S. Public Health Service, state and local health departments, the Division of Social Protection (Federal Security Agency), the U. S. Army, the American Social Hygiene Association and affiliates, the National Tuberculosis Association and affiliates or any recognized volunteer agency of comparable caliber.

(b) A college degree and at least three years of practical experience in some phase of public health work with one or more of the organizations specified.

(c) In lieu of a college degree, a minimum of two years of college credits normally leading to a degree, plus (1) at least three years of practical experience in some phase of public health work, one year of which must have been in venereal disease control, or (2) at least four years of experience in one or more of the following fields: health education with public, private or voluntary agencies; newspapers, advertising or public relations work; community or trade organizations, home demonstration or extension work, or adult education.

With regard to physical requirements, consideration to granting waivers for physical defects will be given candidates whose deficiencies are not such as to interfere with the performance of duty. Desirable candidates should be those who appreciate the necessity of venereal disease control, who would be interested in helping establish proper preventive measures and who would be able to express themselves before groups.

NAVY AWARDS AND COMMENDATIONS

Lieutenant (jg) Laurie Willard Higgins

The Silver Star was recently awarded to Lieut. (jg) Laurie Willard Higgins, formerly of San Diego, Calif. The citation read "for conspicuous gallantry and intrepidity while serving with the First Marine Division on Cape Gloucester, New Britain, Jan. 8, 1944. Traveling almost a mile through constant sniper fire in answer to a call for help from a friendly contingent, Lieutenant, Junior Grade, Higgins courageously administered expert medical aid to the wounded despite the presence of snipers, shielding the injured men from further casualty with his own body. Later he advanced to the battalion observation post, where he rendered urgently needed assistance to wounded men in the face of extremely heavy mortar and sniper fire until it was necessary for him to return to base. Then, organizing his party, he daringly led it through a sniper infested route to his battalion aid station. By this valiant conduct, outstanding

professional skill and disregard for personal safety, Lieutenant, Junior Grade, Higgins contributed materially to the saving of many lives and his actions throughout were in keeping with the highest traditions of the United States Naval Service." Dr. Higgins graduated from the University of Michigan Medical School, Ann Arbor, in 1942 and entered the service July 8, 1943.

Lieutenant (jg) William J. Waters

Lieut. (jg) William J. Waters, formerly of Syracuse, N. Y., was recently commended by the commander, U. S. Naval Forces in Europe. The letter of commendation read:

"Your performance of duty on July 8, July 18 and July 21, 1944, when the base to which you were attached was attacked and partially destroyed by flying bombs, has come to my attention.

"Your assumption of responsibility in the evacuation of casualties and in the immediate treatment of the injured was exemplary and did much to alleviate the suffering.

"For your outstanding initiative and unusual sense of responsibility, you are hereby commended.

"A copy of this letter will be forwarded to the Chief of Naval Personnel to be filed in your official record."

Dr. Waters graduated from Syracuse University College of Medicine in 1942 and entered the service in June 1943.

Lieutenant Ralph Emile Kirsch

Lieut. Ralph E. Kirsch, formerly of Safety Harbor, Fla., was recently commended "for exceptional services as flight surgeon attached to Photographic Squadron 4 operating in the Pacific Area from May to September 1944. Voluntarily participating in hazardous flights over heavily defended enemy targets in the interest and advancement of aviation medicine, Lieutenant Kirsch made and recorded valuable observations under fire and, by the special technics of his own devising, demonstrated the important physiologic changes brought about by such flight circumstances. Lieutenant Kirsch's splendid initiative and expert professional skill in obtaining vital scientific data in the face of grave personal danger were in keeping with the highest traditions of the United States Naval Service." Dr. Kirsch graduated from the University of Chicago School of Medicine in 1939 and entered the service Feb. 22, 1943.

Lieutenant Thomas Edward Bailly Jr.

The Navy and Marine Corps Medal was recently awarded to Lieut. Thomas E. Bailly Jr., formerly of San Francisco. The citation read "for heroic conduct in rescuing a seaman from drowning at Tutuila, Samoa, on July 22, 1943. Hearing cries for help from a man who had been caught in a rip tide and swept beyond the reef, Lieutenant (then Lieutenant, Junior Grade) Bailly unhesitatingly dashed into the water and, completely disregarding his own safety and the difficult conditions attendant on such an attempt, courageously swam to the exhausted helpless man and returned him close enough inshore to permit a life line to reach them. Lieutenant Bailly's splendid initiative and unselfish efforts at great personal risk saved the life of his comrade and were in keeping with the highest traditions of the United States Naval Service." Dr. Bailly graduated from the University of California Medical School, San Francisco, in 1940 and entered the service Dec. 21, 1942.

Lieutenant Joseph M. Foley

The Bronze Star was recently awarded to Lieut. Joseph M. Foley, formerly of Dorchester, Mass. The citation accompanying the award read "for meritorious performance of duty as a company medical officer of the Second Beach Battalion during the assault on France, June 6, 1944. Lieutenant Foley under heavy gunfire repeatedly exposed himself to administer to the wounded and, without regard for his personal safety, supervised the evacuation of wounded from his section of the beach. His courage and devotion to duty were an inspiration to all officers and men having contact with him. The skill and professional ability displayed by Lieutenant Foley under most trying conditions were in keeping with the best traditions of the United States naval service." Dr. Foley graduated from Harvard Medical School, Boston, in 1941 and entered the service Feb. 22, 1943.

MISCELLANEOUS

MILITARY DEATH LOSSES

According to the statisticians of the Metropolitan Life Insurance Company, New York, military death losses in action for all belligerents during 1944 probably exceeded 2 million. They estimate that the battle toll of the Axis countries was about 1¼ million, while the Allies lost considerably less than a million men. The year 1944 was the third in succession in which the military death toll approached or exceeded the 2 million mark and the fourth in succession in which the year's toll was on a scale comparable to the annual losses in the first world war. American battle losses last year, estimated at 1,450,000, were the greatest ever suffered in any year in our entire history. This estimate is based on official reports and includes allowances for deaths among the wounded and missing as well as for the inevitable delay in the receipt of death reports.

While the aggregate losses for all belligerents were about equal in the past two years, our losses last year were about five times as many as in 1943 and more than three times as many as in the whole twenty-five months from Pearl Harbor to the end of 1943. On the Western front alone our losses in 1944 exceeded our total for all of the first world war. However, the maximum monthly rate reached in December 1944 was about the same as the monthly peak of the first world war in October 1918, when 19,000 of our men were killed in action. More than four fifths of American losses during 1944 were in the Army, and losses among the Marines, mainly in Pacific area land fighting, accounted for about half of the Navy's total. Considering the scale of fighting by our fleet last year, the battle toll among ship personnel was relatively small.

Japan admitted that 168,000 of her men were killed and wounded in 1944, but compilation of figures covering the various operations in the Pacific and East Asia indicates that her death losses actually were upward of 350,000 and may have exceeded 400,000. The sinking of troop transports and barges accounted for a significant proportion of this total, while her naval personnel lost heavily, particularly in the two major battles of the Philippine Sea.

The Germans have been completely silent for more than two years past regarding their current losses. On the Russian front, where most of these were sustained, their combat deaths probably equaled or exceeded those of the Russians. From a careful review of the events on all Germany's fighting fronts a conservative estimate of her death toll in action in 1944 would be 800,000 men. Various higher estimates published on German losses must be viewed in the light of the fact that Germany has increasingly used nationals of conquered territories in her armies and has ruthlessly sacrificed them.

The statisticians place Russian battle losses in 1944 around 550,000 men. With Russia continuing to bear the brunt of land action against the Nazis last year, the scale and tempo of the fighting, as well as the bitter struggles for key areas such as Warsaw and Budapest, exacted a heavy toll in the aggregate. Much of Russia's gains last year, however, represented territory yielded by the Germans with little more than rear guard fighting, and these cost the Russians relatively few battle casualties.

The operations of British Empire forces increased greatly during 1944 on the Western front, the Mediterranean area, in Burma and in the air over Europe, the statisticians point out. The British navy contributed greatly also to the naval protection of the Atlantic sealanes and the invasion beach heads in France. These far flung actions cost the empire an estimated 125,000 men. At least two thirds of these were from Britain.

The aggregate losses last year among the other allies were considerable, with 10,000 to 15,000 Frenchmen killed in action on the Western front and in other operations. In the Allied total are included many thousand dead in the various contingents of Yugoslavs, Norwegians, Dutch, Belgians, Greeks, Poles and Czechs fighting on our side in Europe, while the Chinese may have lost as many as 50,000 men in the fighting in Burma and in China itself.

Battle losses of the former Axis satellites last year probably reached 100,000. The greater part was borne by Rumanian troops in southern Russia, in the Crimea and in the final engagements leading to their surrender. Hungary lost about half as many as Rumania, largely during the Russian invasion.

MEDICAL ADVISORY GROUP TO
THE ADMINISTRATOR OF
VETERANS' AFFAIRS

Brig. Gen. Frank T. Hines, administrator of veterans' affairs, recently announced the names of fourteen members of the special medical advisory group to the administrator of veterans' affairs. When it is completed, the group is planned to have fifteen members. Those who have accepted the invitation to serve in this group are Dr. George Morris Piersol, Philadelphia; Dr. Roy D. Adams, Washington, D. C.; Dr. John Alexander, Ann Arbor, Mich.; Dr. J. Burns Amberson Jr., New York; Dr. George E. Bennett, Baltimore; Dr. William F. Lorenz, Madison, Wis.; Dr. Frederick W. Parsons, New York; Dr. Oliver H. Perry Pepper, Philadelphia; Dr. Irvin Abell, Louisville, Ky.; Dr. Alfred W. Adson, Rochester, Minn.; Dr. W. Edward Chamberlain, Philadelphia; Dr. John S. Coulter, Chicago; Dr. Malcolm T. MacEachern, Chicago, and Capt. Erik G. Hakanson, Bethesda, Md. General Hines stated that this group will guide him in establishing policies and in solving the many perplexing problems that face the administration in the examination and treatment of thousands of young veterans who are being hospitalized from this war. One of the primary problems is securing and training the highly qualified professional and subprofessional personnel needed to care for the increasing number of hospital patients and expanding outpatient group coming to the Veterans Administration. Their services are also expected to be invaluable in outlining and assaying research work in war medicine and making recommendations as to the desirability of results for incorporation in clinical and therapeutic practices in veterans' hospitals. This phase of their work will include important decisions as to the extent to which teaching and research activities should be expanded in the Veterans Administration.

MELLON HOME MAY BE CLUBHOUSE
FOR WOMEN OFFICERS

The home in Washington, D. C., of the late Andrew W. Mellon, former Secretary of the Treasury, may be converted into a home and club house for women officers in the medical departments of the armed forces, according to Mrs. Norman T. Kirk, wife of the surgeon general of the Army and president of the Medical Women Army and Navy Club. The home is the property of Stanley McCormick of Chicago and is now occupied by the British Ministry of Aircraft Production. An offer to purchase the five story house has been made by the club. The club is designed to provide hotel accommodations and recreational facilities for army and navy nurses and women doctors. The club has the sponsorship of General Kirk and Vice Admiral Ross T. McIntire, surgeon general of the Navy. Wives of cabinet members and Army and Navy leaders serve on the board of the club.

PRISONERS OF WAR

The State and War departments recently announced that to effect a further exchange with Germany of seriously sick and wounded prisoners of war eligible for repatriation under the Geneva Convention the T. M. V. Gripsholm is en route to Marseilles. Included in the group for exchange will be a number of German civilians in the custody of the United States and Mexico to be repatriated in exchange for United States nationals and nationals of certain other American republics. The last exchange took place in September 1944. The Gripsholm will return to New York in late February. As soon as the identity of the repatriates has been established beyond possibility of a doubt, the next of kin of American personnel will be notified.

DR. FRIDGEIR OLASON AND FAMILY
LOST AT SEA

Dr. Fridgeir Olason of Reykjavik, Iceland, lost his life when the boat on which he was returning home last November was torpedoed by a German U-boat. He was a passenger on the Godafoss, sunk in Icelandic waters with a loss of twenty-five lives. His wife and three children also were lost. Dr. Olason

received his M.D. degree from the University of Iceland in 1938. He then served as a public health physician in a rural district in Iceland. In 1942 he came to Vanderbilt University School of Medicine, Nashville, Tenn., where the degree of master of public health was conferred on him in 1943. He then went to Harvard Medical School, Boston, where he completed work for the degree of doctor of public health, the degree being awarded posthumously Nov. 28, 1944. His wife was also a physician and worked in the county health department.

TWO CHURCHES FINANCE MEDICAL UNIT FOR ITALY

Provided with funds from the Congregational Christian and Unitarian churches, the first privately financed American medical unit organized to aid war stricken Italians will be ready for action in a few months. Dr. Elmer L. Sevringhaus, professor of medicine at the University of Wisconsin, recently disclosed that the two denominations have allocated \$100,000 for the unit and promised "additional funds when needed." The unit will include eight physicians, two dentists, two laboratory technicians, one dietitian and two executive officers. Dr. Maurice B. Visscher of the University of Minnesota is aiding Dr. Sevringhaus in organizing the unit.

The purpose of the mission will be to study control of epidemics and the spread of tuberculosis among undernourished people, as well as diseases of underfed children.

RUSSIAN WAR RELIEF, INC.

Almost \$23,000,000 in cash and goods was contributed by the American people during 1944 to Russian War Relief, making a total of \$46,246,240 received by the agency since its inception a little more than three years ago. Eugene D. Kisselev, Soviet consul general, recently expressed the appreciation of his government and people for America's aid through Russian War Relief. Mr. Edward C. Carter is president of Russian War Relief, Inc. (5 Cedar Street, New York 5).

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Services:

(Continuation of list in THE JOURNAL, February 17, page 404)

CALIFORNIA

Mount Zion Hospital, San Francisco. Capacity, 193; admissions, 5,333. Dr. J. A. Katzive, Director (resident—roentgenology, disqualified for military service).

NEW JERSEY

St. Francis Hospital, Trenton. Capacity, 355; admissions, 8,795. Sister M. Regulata, R.N., Superintendent (interns, residents).
North Hudson Hospital, Weehawken. Capacity, 191; admissions, 2,938. Dr. J. Lawrence Evans, Administrator (interns).

NEW YORK

Wyoming County Community Hospital, Warsaw. Capacity, 142; admissions, 2,581. Dr. C. F. Mignin, Superintendent (residents—mixed service, July 1).

OHIO

Deaconess Hospital, Cincinnati. Capacity, 198; admissions, 4,399. Mr. William H. Frersing, Superintendent (2 interns, July 1; 2, August 1). Lima Memorial Hospital, Lima. Capacity, 182; admissions, 5,300. Mr. Leslie O. Fonkalsrud, Administrator (3 interns, July 1).

PENNSYLVANIA

Hahnemann Hospital, Philadelphia. Capacity, 616; admissions, 10,548. Dr. R. W. Plummer, Medical Director (residents—medicine, surgery, pediatrics, anesthesia, disqualified for military service).

TEXAS

Methodist Hospital, Dallas. Capacity, 225; admissions, 8,193. Dr. C. W. Sensesbach, Medical Director (interns, residents, now and July 1).
St. Paul's Hospital, Dallas. Capacity, 300; admissions, 12,444. Sister M. Antonia, R.N., Superintendent (interns, resident, now and July 1).

WISCONSIN

Luther Hospital, Eau Claire. Capacity, 176; admissions, 4,006. Mr. N. E. Hanshus, Manager (interns, March 15 to July 15).

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Induction Center, Grand Central Palace, New York: Clinical Implications in the Newer Knowledge of the Shock Syndrome, Dr. Samuel Standard, March 2; Early Diagnosis of Syphilitic Heart Disease, Dr. Edwin P. Maynard Jr., March 9 (to be repeated March 16); Report on Anesthesia Practice in the Present War, Dr. E. A. Rovenstine, March 23.

Newton D. Baker General Hospital, Martinsburg, W. Va.: Penetrating Wounds of the Abdomen, Dr. Arthur M. Shipley, March 5; Diagnosis and Treatment of Cardiovascular Conditions Peculiar to Military Life, Dr. Louis Hamman, March 5; Experiences with Malaria, Col. Paul F. Russell, March 19; Diagnosis of Diarrheal Diseases, Lieut. Col. Hardy Kemp, March 19.

A. A. F. Regional Hospital, Langley Field, Virginia: Preservation and Restoration of Function of the Extremities, Dr. W. T. Graham, March 30; Psychiatry, Dr. R. Finley Gayle, March 30.

Tilton General Hospital, Fort Dix, New Jersey: X-Ray Analysis of Fractures, Dr. W. Edward Chamberlain, February 26.

Percy Jones General and Convalescent Hospital, Battle Creek, Mich.: Surgical Diseases of the Stomach, Dr. Warren H. Cole, February 26.

Station Hospital Truax Field, Wisconsin: Heart Disease, Dr. Chester M. Kurtz, February 28; Arthritis, Dr. Milton C. Borman, March 14; Peripheral Vascular Diseases, Dr. Geza de Takats, March 28.

Station Hospital, Rosecrans Field, St. Joseph, Mo.: Gastrointestinal Diseases, Dr. R. C. Davis, March 8; X-Ray Diagnosis, Dr. Ira H. Lockwood, March 8.

Birmingham General Hospital, Van Nuys, Calif.: Thoracic Surgery, Dr. John Jones and Lieut. Comdr. J. E. Dailey, February 28; Chemotherapy, Dr. Clinton Thienes and Lieut. Comdr. Charles Bingham, March 14; Coccidioidomycosis, Drs. E. M. Butt and Ray A. Carter, March 28.

Station Hospital, U. S. Naval Air Station, North Island, San Diego, Calif.: Pathogenesis of Rheumatic Fever, Lieut. Comdr. Robert W. Huntington Jr., March 2; Clinical Aspects and Treatment of Rheumatic Fever, Lieut. Comdr. George C. Griffith, March 2; Internal Derangements of the Knee, Dr. John Wilson, March 16.

Wakeman General Hospital, Camp Atterbury, Indiana: Conditions Affecting Glucose Metabolism, Drs. Franklin B. Peck and C. L. Rudesill, February 28.

Billings General Hospital, Fort Benjamin Harrison, Indiana: High Blood Pressure, Drs. Kenneth G. Kohlstaedt and Robert L. Glass, February 28.

Regional Hospital, Camp Haan, Calif. (March Field will meet with Camp Haan): Anesthetic Morbidity, Capt. E. H. Warnock, March 6; Some Practical Pointers in Anesthesia, Lieut. John E. Skewis, March 6.

Torney General Hospital, Palm Springs, Calif. (medical staffs of U. S. Navy convalescent hospitals at Banning and Beaumont will meet with this group): Recent Developments in Surgical and Public Health Antisepsis, Dr. Frederick J. Moore, March 6.

A. A. F. Regional Hospital, Santa Ana Air Base, Santa Ana, Calif.: Pathogenesis of Rheumatic Fever, Lieut. Comdr. Robert W. Huntington Jr., March 6; Clinical Aspects and Treatment of Rheumatic Fever, Lieut. Comdr. George C. Griffith, March 6.

U. S. Naval Hospital, Corona, Calif.: Atypical Pneumonias, Dr. W. E. Macpherson, March 8; X-Ray Observations, Lieut. A. B. Phillips, March 8.

U. S. Naval Hospital, Oceanside, Calif.: Blood Plasma and Substitutes, Lieut. Col. R. M. Jones, March 8; Water Balance, Major Edward Schwartz, March 8.

United States Naval Air Training Station, San Diego, Calif.: Pathogenesis of Rheumatic Fever, Lieut. Comdr. Robert W. Huntington Jr., March 2; Clinical Aspects and Treatment of Rheumatic Fever, Lieut. Comdr. George C. Griffith, March 2.

Station Hospital, Camp Cooke, California: Classification and Diagnosis of Anemias, Dr. Alvin Foord, March 7.

Hoff General Hospital, Santa Barbara, Calif.: Classification and Diagnosis of Anemias, Dr. Alvin Foord, March 7.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Feb. 19, 1945.

War Production Board Aids Medical Research

In addition to other technical accomplishments, the Office of Production Research and Development of the War Production Board has chalked up records in the medical field. Among its efforts has been assistance in the building of DDT insecticide plants, in the production of penicillin, in the conservation of eyesight in industry, in the synthesis of quinidine and in speeding up the manufacture of dental burrs. In regard to penicillin, the OPRD has coordinated the technological aspects of the conversion from laboratory to plant processes in penicillin manufacture. It is estimated that this has advanced the plant program of penicillin production about three months. Three new strains of penicillin mold have been developed in OPRD projects. These strains are capable of producing two to three times as much penicillin as those originally used. Millions of dollars in plant construction are said to have been saved by these strains. A practical and efficient synthesis of quinidine, used for certain heart diseases, was developed with quinine as the raw material. The production of synthetic quinidine is important because of the current shortage of imported quinidine. A new and faster machine for manufacturing dental burrs was also developed by an industrial concern under OPRD sponsorship.

Commissioning Male and Female Nurses Proposed

The House Military Affairs Committee has tentatively given its stamp of approval to making male as well as female nurses eligible for commissions as second lieutenants. It also favors a proposal of Representative Sparkman, Democrat of Alabama, to include not only registered nurses but all those who are eligible for commissioning as nurses in proposed draft legislation. It is also in support of a move to raise the minimum age for drafted nurses from 18 to 20 years, with the maximum age limit remaining at 45. An amendment will probably be attached to the May nurse draft bill making graduates of the Cadet Nurse Corps liable for induction first. These items were considered by the committee in closed session.

Navy Calls for 3,000 to 4,000 More Nurses

As its assaults come nearer to Tokyo and the Japanese-occupied Asiatic mainland, the Navy has appealed for 3,000 to 4,000 more nurses to care for wounded men and to train thousands of corpsmen (both men and women). The Navy's nurse recruits, starting as ensigns, will join the corps of 9,000 nurses already serving. Navy nurses are on duty here and overseas, on hospital ships, transports and ambulance planes and in base hospitals. In the Navy recruits must have graduated from high school, be from 22 to 28 years of age or up to 40 in the reserve corps, and not be married, widowed or divorced. First duty will be to supervise personnel of little or no previous nursing experience.

Capital Contributes \$250,000 to Poliomyelitis Fund

Commissioner John Russell Young reveals that Washington contributed approximately \$250,000 to the infantile paralysis fund campaign. The District of Columbia's ranking official is now busy receiving on behalf of the Washington fund substantial contributions toward the mile of dimes campaign. Large amounts were raised through the President's birthday balls in Washington and throughout the nation.

Extra Medical Supplies Flown to Germany

Red Cross headquarters reveals here that extra medical supplies from Geneva are being rushed to prisoner of war camps in western Germany to prevent epidemics. The transfer to the west by Germany of thousands of prisoners in the path of the

advancing Russian army has caused extreme overcrowding. Increased shipments from the United States include a load of typhus vaccine in refrigerated cases, flown by air express to Europe. A special staff has been set up in the American Red Cross prisoners of war relief section to expedite the work.

Artificial Limb Production to Be Standardized

Army, Navy and Veterans Administration officials conferred in Chicago with manufacturers of artificial limbs to agree on standardized limbs to be issued to, disabled service men by the three agencies. The Veterans Administration reports that standardization will simplify the making of repairs and replacements. Its contracts allow for the payment of \$290 for full length metal legs in amputations where the hip is disarticulated, \$165 in the usual below knee amputation and \$215 in the usual thigh amputation.

Rheumatic Fever Threat Feared in Washington

Dr. Bernard J. Walsh, District Health Department cardiologist, has warned that many more children are likely to be attacked this spring by rheumatic fever, a crippling disease, owing to extreme overcrowding in the capital. Already more than 150 children are registered in the Crippled Children's Clinic at Gallinger Hospital suffering from rheumatic heart disease as a result of the fever.

Dispensary Facilities in Government Buildings

Properly situated first aid and dispensary facilities will be included in government buildings built after the war, the Federal Interdepartmental Safety Council reports. A plan has been drawn whereby agencies planning new buildings can specify these requirements in cooperation with the U. S. Public Health Service.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Changes in Status.—The Senate Committee on Education and Labor has scheduled hearings on S. 191, the Hill-Burton hospital construction bill, to begin February 26. H. J. Res. 109 has passed the House and has been reported to the Senate, proposing an additional appropriation of \$184,000 for the United States Public Health Service. This appropriation is to be utilized in the leasing and repair of the 300 bed hospital facility known as the Neponsit Beach Hospital at Rockaway Beach, Long Island, from the city of New York. The city has agreed to lease the hospital for the official duration of the war at a rental of \$1 for the first year and at the rate of \$30,000 per year thereafter. The purpose of the lease is to permit the removal of tuberculous patients from Staten Island Marine Hospital and thus enable that hospital to meet such demands as may be made on it as long as the war continues. The House Committee on Military Affairs has been conducting hearings on H. R. 1284 and H. R. 1666, proposing the drafting of nurses. A bill will be reported shortly, it is understood. S. Res. 62 has been reported to the Senate, proposing an additional appropriation of \$15,000 to permit the Pepper Subcommittee on Wartime Health and Education to continue its study and survey of the distribution and utilization of health personnel, facilities and related services.

Bills Introduced.—S. 535, introduced by Senator Myers, Pennsylvania, proposes to prevent pollution of the waters of the United States and to correct existing water pollution. The bill would create a National Board of Water Pollution Control, consisting of the Secretary of the Interior, Secretary of Agriculture, Secretary of War, Secretary of the Navy, Surgeon General of the Public Health Service and the chairman and ranking minority member of the Senate Committee on Com-

merce and of the House Committee on Rivers and Harbors. H. R. 1362, introduced by Representative Crosser, Ohio, proposes to amend the Railroad Retirement Acts and the Railroad Unemployment Insurance Act so as to provide, among other things, sickness and maternity benefits for employees. H. R. 2044, introduced by Representative Weiss, Pennsylvania, proposes to enact a United States Physical Fitness Act and to establish a United States Commission of Physical Fitness to carry out the purposes of the act. H. R. 2066, introduced by Representative De Lacy, Washington, and H. R. 2133, introduced by Delegate Bartlett, Alaska, propose to authorize the Secretary of the Interior to locate, establish, construct, equip and operate a hospital for the insane of Alaska. H. R. 2075, introduced by Representative Reece, Tennessee, provides that any ex-service person shown to have had a tuberculous disease of a compensable degree shall receive, under certain circumstances, not less than \$62.50 per month. H. R. 2139, introduced by Representative Gathings, Arkansas, would authorize the Federal Works Administrator to cause hospital projects initiated under the Lanham Act to be completed and equipped. H. R. 2206, introduced by Representative Harris, Arkansas, contemplates the establishing of a presumption of service-connected disability in the case of disease or injury existing within five years after discharge from service in the armed forces during the present war.

STATE LEGISLATION

Arkansas

Bill Introduced.—H. 249 proposes that no person "legally registered as a member of any trade or profession" shall be required to reregister or to pay a fee for same unless his license has been revoked for legal cause.

California

Bills Introduced.—S. 1010 proposes to condition the manufacture or sale of vitamins on the possession of a license for that purpose issued by the state board of health. The standards of purity of vitamins to be enforced by the board are to be as set out in the United States Pharmacopeia, the Homeopathic Pharmacopeia of the United States and the National Formulary. A. 1344 proposes, whenever it is relevant to the prosecution or defense of an action, that the court may order any party whose paternity is relevant to the issues in the action to submit to blood grouping tests. The results of those tests are to be admissible in evidence if definite exclusion of paternity of the person tested is indicated. A. 1427 proposes to add to the Health and Safety Code a division 22, entitled "Dangerous Drugs," which proposes to prohibit the sale or distribution of any dangerous drug except on the written prescription of a licensed physician, dentist, chiropodist or veterinarian. Dangerous drug is defined to mean any hypnotic drug, aminopyrine, amphetamine, cinchophen, diethylstilbestrol, ergot, oils of croton, rue, savin or tansy, sulfanilamide and thyroid. A. 1678, to amend the medical practice act, proposes to authorize the board of medical examiners to issue a herb practitioner's certificate.

Connecticut

Bills Introduced.—S. 238 proposes to enact a separate massage practice act and to authorize local health officers to license persons so to practice. S. 524 proposes to direct the governor to appoint a commission of five to study and investigate the subject of health insurance and to report its findings and recommendations to the next session of the general assembly. H. 601 proposes to set up a system of compulsory health insurance. H. 999 proposes to authorize the Connecticut Hospital Service, Inc., to enter into contracts with and to act as agent for any medical service corporation.

Georgia

Bills Introduced.—H. 175, to amend the narcotic drug act, proposes so to define narcotic drugs as to include isonipecaine, which, the bill provides, means "the substance identified chemically as 1-methyl-4-phenyl-piperidine-4-carboxylic acid ethyl ester, or any salt thereof whether known as Demerol or by whatever other trade name identified." H. 122, to supplement

the medical practice act, proposes to authorize the state board of health to make such reasonable rules and regulations concerning the certification of midwives and the practice of midwifery as it may deem necessary and to provide that those rules and regulations shall have the effect of law. A person so licensed by the board of health is to be entitled legally to practice midwifery in cases of normal labor and in no other and may not in any case use instruments of any kind or assist labor in any artificial, forcible or mechanical manner or attempt to remove adherent placentas or to introduce either fingers or any other object whatsoever into the vagina.

Idaho

Bill Introduced.—H. 119, to amend the laws relating to the practice of chiropractic, proposes, among other things, that in appointing members of the board of chiropractic examiners the governor must confine his choice to persons nominated by the state chiropractors association.

Illinois

Bills Introduced.—H. 95 proposes to permit townships to operate public nonsectarian hospitals if authorized by the electors of the township. H. 103 proposes to prohibit the operation of a "private hospital" unless licensed by the Department of Registration and Education. Private hospital means "every private hospital, nursing home, resting home and sanitarium, for persons requiring care, treatment or nursing, by reason of sickness, injury, deformity or other disability."

Indiana

Bills Introduced.—S. 193 proposes to enact a separate practice act relating to naturopathy and physiotherapy and to create a board of natural therapeutic physicians to examine and license applicants for licenses to practice in the fields indicated. H. 308 proposes to authorize Indiana University to establish a department of public health and to offer courses of instruction in that field. H. 390 proposes to prohibit the operation of a hospital without a license from the state board of health. Hospital is defined as "any institution, place, building or agency represented and held out to the general public as ready, willing and able to furnish care, accommodations, facilities and equipment for the use, in connection with the service of a physician, of persons who may be suffering from deformity, injury or disease or from any other condition for which medical or surgical services would be appropriate for care, diagnosis or treatment." The term does not include convalescent homes, boarding homes, homes for the aged or hospitals for the insane or for those suffering from other mental conditions. H. 449 proposes to enact what apparently is the uniform vital statistics act providing for the collection and compilation of records of births and deaths.

Iowa

Bill Introduced.—S. 280, to amend the laws relating to the practice of chiropractic, proposes that such a license shall not authorize the holder to prescribe, furnish or sell vitamins or to employ in his practice x-ray machines for any purpose.

Kansas

Bill Introduced.—H. 140 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a certificate of a physician, based on physical examination and on serologic tests, that the party is not infected with syphilis, or, if so infected, the disease is not in a stage which is communicable to a marital partner.

Maine

Bills Introduced.—S. 211 proposes that, when a patient being treated by a physician for venereal disease discontinues treatment while capable of transmitting the disease to others, the physician shall report the name and address of the person at once to the bureau of health. S. 212 proposes to condition school attendance on the presentation by the child of evidence that he or she has been inoculated with the virus of cowpox to prevent smallpox and, if the child is under 12 years of age,

on the presentation also of a physician's certificate that the child has been immunized against diphtheria. Evidence of such inoculation and immunization may be waived on the written statement of a physician that the condition of the child is such that inoculations would be injurious to health or on the presentation of a written statement from the parents that they object to such inoculations because of religious belief. S. 215 proposes, in effect, to permit osteopaths to sign certificates for committing persons to state institutions and to participate in health services under the department of health and welfare the same as physicians of other schools of medicine. The bill also proposes to dub practitioners of osteopathy as "osteopathic physicians." H. 844 proposes to direct the department of health and welfare to survey all existing public and private hospitals and health centers in the state, to evaluate the sufficiency of existing facilities to supply necessary medical and hospital care to the people, and to accept any available federal or other funds for public health services of all kinds. H. 843 proposes that no school employee shall assume the performance of his duties until he has filed with the appropriate school committee a physician's certificate that he is free from communicable and infectious diseases.

Massachusetts

Bills Introduced.—H. 858, to amend the medical practice act, proposes to make eligible for examination and licensure persons who matriculated at Middlesex University during 1941, have graduated therefrom and who subsequently have served as interns in a hospital. H. 964 proposes to enact what appears to be the uniform vital statistics law respecting the registration, compilation and preservation of births, deaths and stillbirths. H. 1511 proposes that the state establish and operate the Massachusetts university of medicine to furnish instruction in the practice of medicine.

North Carolina

Bill Introduced.—H. 229 proposes to authorize the state board of health to promulgate rules and regulations governing the sanitation of all private hospitals and to inspect the premises of such institutions to see that they conform to the regulations so promulgated.

North Dakota

Bills Introduced.—S. 127 proposes to make it unlawful for any insurance company doing business in the state to issue any sickness or accident insurance policy wherein the insured is denied the right to consult or employ the services of any licensed practitioner of his choice. Such insurance companies are to be required to recognize the certificate of any licensed practitioner "the same as that of any licensed physician and surgeon." H. 187 proposes to authorize the formation of a nonprofit medical service corporation to operate medical service plans whereby medical service is provided at the expense of the corporation to subscribers needing it. H. 236 proposes that every contract by which any one is restrained from exercising a lawful profession is to that extent void.

Oregon

Bills Introduced.—S. 151, to amend the medical practice act, proposes to increase to \$10 from \$5 the annual registration fee required of licensed physicians and osteopaths. H. 307 proposes that the person in charge of any conveyance in which or by which another is injured, unless instructed otherwise by the injured person, shall immediately take the injured person to the nearest hospital for attention. The bill further provides that the temporary treatment of an injured person under emergency conditions by an unlicensed person shall not constitute the unlawful practice of medicine.

Pennsylvania

Bills Introduced.—S. 239 proposes to authorize the sexual sterilization of certain socially inadequate inmates of state institutions. H. 377 proposes to prohibit any person from experimenting or operating in any manner whatsoever on any living dog for any purpose other than the healing or curing of such dog of physical ailments.

South Dakota

Bill Introduced.—S. 160 proposes to authorize the formation of nonprofit medical service plan corporations to operate medical service plans under which medical services may be rendered to subscribers and covered dependents by licensed physicians at the expense of the corporation in consideration of periodic prepayments made prior to the occurrence of the condition calling for the rendition of medical services.

Tennessee

Bill Introduced.—S. 522 proposes to authorize the formation of nonprofit medical service plan corporations to operate medical service plans under which medical services may be rendered to subscribers and covered dependents by a licensed physician at the expense of the corporation in consideration of periodic prepayments made prior to the occurrence of the condition called for the rendition of medical service.

Utah

Bill Introduced.—H. 176 proposes to make it unlawful for any person, firm or corporation to dispense any corrective eye glasses, lens or spectacles except on the prescription of a licensed physician or optometrist.

Washington

Bills Introduced.—S. 138 proposes to enact a separate act regulating the practice of massotherapy and to create a committee of examiners in massotherapy to examine and license applicants for a license to practice massotherapy. The bill proposes to define massotherapy as "the method, art or science of treating the human body for hygienic or remedial purposes to maintain health and to establish a normal condition of the body and shall include all massage manipulations, passive and active remedial gymnastics and relaxing movements and manipulations with the hands or with any other agency or instrumentality designed to accomplish massage manipulations or gymnastics, or by mechanical gymnastics to promote physiological action to bring about a normal condition of health and restore bodily functions to a normal condition." S. 149 proposes to authorize the formation and operation of nonprofit hospital service corporation to provide hospital service plans whereby hospital care may be provided at the expense of the corporation to subscribers to such plans. S. 171 proposes to impose a liability on all hospitals, whether charitable or otherwise, for damages that may result to patients, whether free or pay, by reason of the negligent conduct of hospital employees.

Official Notes

LARGEST NETWORK IN AMERICAN MEDICAL ASSOCIATION BROADCASTING HISTORY

A report just received from the National Broadcasting Company indicates that Doctors Look Ahead is now being broadcast on 123 National Broadcasting Company stations from coast to coast and from border to Gulf. Except for certain radio "dead-spots" where listening is interfered with by atmospheric or electrical phenomena, Doctors Look Ahead should be available to listeners everywhere.

This wide acceptance of a nonrevenue program by local stations is evidence of its high acceptability to local program directors who understand the needs and preferences of their listening audiences. A nonrevenue program such as Doctors Look Ahead, although furnished to all local stations by the network, may be ignored by the local station in favor of its own local programs. Unless the net program is of high quality, this is frequently what happens. The next three subjects for Doctors Look Ahead are as follows:

February 24: The Discharged Soldier.
March 3: Nutrition at Home (Dr. G. K. Anderson).
March 10: Rheumatic Fever.

The Bureau of Health Education, which directs Doctors Look Ahead, will welcome suggestions from listeners.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CONNECTICUT

State Meeting Canceled.—The Connecticut State Medical Society announces the cancellation of its meeting which was scheduled to be held in Hartford, May 1-3.

Position Available as Health Consultant.—Applications are being accepted by the state of Connecticut, Hartford, for examination to fill the position now available as local health consultant. Applications will be accepted until March 31. The applicant must be eligible for a license to practice medicine and surgery in Connecticut and must have not less than five years' employment in public health work including experience as health officer of a municipality, county or district; or similar experience of at least three years' duration and completion of graduate training in public health work or an equivalent of the two. Connecticut residence requirement is waived for the examination. Candidates must be citizens of the United States. The salary range is from \$5,100 to \$5,700 a year. Additional information may be obtained from the Personnel Department, State Capitol, Hartford.

ILLINOIS

Physician Starts Forty-Fifth Year as Coroner.—Dr. Joseph B. Schreiter, Savanna, recently started his forty-fifth year as coroner of Carroll County. Dr. Schreiter, who graduated at Rush Medical College, Chicago, in 1896, was named coroner in 1900, serving in the position ever since with time off to go overseas in the first world war.

Tuberculosis Patch Test.—Hal Hall, Ed.D., superintendent of the Campus Laboratory Schools, writes to correct information that he submitted to THE JOURNAL concerning the series of patch tests that were given to 150 students in the Allyn Elementary School, Carbondale. Mr. Hall states that 1 active case reported should have been "arrested" case of tuberculosis (THE JOURNAL, February 10, p. 345).

Charles Siler Named Health Commissioner of Oak Park.—Dr. Charles A. Siler, a practicing physician in Oak Park since 1929 and formerly a medical missionary in China, has been appointed health commissioner of Oak Park, effective February 15. He succeeds Dr. Gilbert P. Pond, who resigned to accept a commission in the U. S. Navy. Dr. Siler graduated at the University of Kansas School of Medicine, Lawrence-Kansas City, in 1910, receiving also a degree from Rush Medical College, Chicago, in 1922.

Chicago

Department of Registration Moves.—The state department of registration and education moved, January 31, to the second floor of the Burnham Building, 160 North La Salle Street. The department, whose telephone number is now Andover 4755, was formerly housed at 600 South Michigan Avenue.

The Edwin Kretschmer Memorial Lecture.—The fourth Edwin R. Kretschmer Memorial Lecture will be delivered on April 27 at the Palmer House by Dr. William Bloom, professor of anatomy, University of Chicago School of Medicine, on "Experiments on Hematopoiesis." The lecture is a project of the Institute of Medicine of Chicago.

Pathology Professorship Created.—A professorship in pathology is one of four new professorships created at Northwestern University in honor of the late Mrs. Emma H. Morrison. Mrs. Morrison willed \$1,750,000 to the university when she died four years ago to create the "Charles E. and Emma H. Morrison Memorial Fund" with the stipulation that the university use the bequest in the manner it deemed best. The other professorships include one each in zoology, English and marketing.

Society News.—Dr. Francis W. Carruthers, professor of orthopedic surgery, University of Arkansas School of Medicine, Little Rock, among others, will address the Chicago Orthopaedic Society, March 9, on "Anatomical and Functional Reductions of Fractures of the Pelvis." Dr. Lee M. Cattell was among the speakers who addressed the February 9 meeting, his subject being "Penicillin Therapy in Acute Osteomyelitis in Children: Ten Consecutive Cases."—Dr. William

D. Stroud, Philadelphia, will address the North Side Branch of the Chicago Medical Society at the Drake Hotel, March 1, on "Heart Disease."—Col. Irving S. Wright, M. C., addressed the Chicago Heart Association, February 15, on "Cardiovascular Highlights of the War." Among others, Dr. Edwin J. Blonder will address the Chicago Laryngological and Otological Society at the Continental Hotel, March 5, on "Visualization of Otic Brain Abscess."

KANSAS

Menninger Institutions Reorganized.—At a recent special meeting of the stockholders of the Menninger Sanitarium corporation, Topeka, a resolution was approved to dissolve the corporation as of next June 30 and to transfer its assets to the Menninger Foundation. The reorganization will promote the expansion program entailing more than \$1,250,000 and would, when permissible, allow a long considered consolidation of activities in education, treatment and research. The transfer in assets will involve buildings, equipment, grounds and other facilities of the clinic on West Sixth Street totaling \$325,000, of which \$200,000 will be a personal contribution of Drs. Charles F., Karl A. and William C. Menninger and their colleagues. According to the Topeka State Journal, an earning capacity of between 70 and 80 thousand dollars annually, along with the good will and prestige of the organization, which has completed twenty-five years, will be additional benefits. Treatment of a larger number of patients, both adults and children, without regard to their financial status, will be a major aim of the foundation, for which a psychiatric hospital unit costing \$750,000 is contemplated. Additional buildings trebling the capacity of the Southard school would cost \$250,000, and a psychosomatic hospital unit for correlation of psychiatric and medical studies was projected at \$150,000. A fund of \$100,000 a year would permit low cost treatment for patients with small incomes. Estimates for postgraduate education, including training for young psychiatrists, physicians returning from military service, nurses, teachers and others, were placed at \$105,000; for research \$149,000, for scholarships for promising children \$30,000, and for publications \$5,000. The Menninger project is an original partnership of the father, Dr. Charles Frederic Menninger, and his two sons and includes a hospital on a 30 acre tract, the Southard school established in 1925 for the treatment of children, a library to further teaching and research and a department of psychology established by Junius F. Brown, Ph.D., professor of psychology, University of Kansas, Lawrence, and continued by David Rapaport, Ph.D. The Menninger Foundation was organized in 1941 (THE JOURNAL, Jan. 10, 1942, p. 154).

MARYLAND

Medical Students Required to Take Course in American History.—Drastic changes in the University of Maryland curriculum, under which all students will be required to take courses in American history, American literature and American government and its philosophy, will go into effect next school year, newspapers reported, February 7. Medical, engineering and law students, as well as those in the liberal arts colleges, will be required to take the courses, that the university may "turn out men and women graduates with a better understanding of the American way of life."

MASSACHUSETTS

Personal.—Dr. Dora E. Brault, formerly assistant health officer in Prince George County, Md., for the U. S. Public Health Service, has been appointed an epidemiologist with the Massachusetts Department of Public Health, Boston.

Henry Pollock Retires as Superintendent of the Massachusetts Memorial Hospitals.—On February 1 Dr. Henry M. Pollock retired as superintendent of the Massachusetts Memorial Hospitals, Boston, a position he had held for thirty years. He has been succeeded by Dr. Leverett S. Woodworth, associate director of Harper Hospital, Detroit. Dr. Pollock graduated at the University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, in 1897 and was appointed to the Massachusetts Memorial Hospitals in 1915. Dr. Woodworth graduated at Cornell University Medical College, New York, in 1926.

Clinic Reorganized.—The Lawrence Clinic has recently been reorganized. According to the New England Journal of Medicine Capt. Glenmore F. Clark (MC), U. S. Navy retired, will direct the clinic, and arrangements have been made with the executive committee of the Lawrence General Hospital,

composed of Drs. Harold R. Kurth, Lawrence; Rolf C. Norris, Methuen; John J. Hartigan, Andover; Z. William Colson, Lawrence; Richard J. Neil, Methuen, and Percy J. Look, Andover, whereby the staff of the Lawrence General Hospital will act as the staff of the Lawrence Clinic. When the work of the clinic increases and more physicians and dentists become available, the program of services will be modified accordingly.

MICHIGAN

St. Mary's Hospital to Observe Centennial.—On May 16-17 St. Mary's Hospital, Detroit 26, will celebrate its one hundredth anniversary. The hospital urges former interns and residents to communicate with it in order that they may be duly recognized during the program.

Secretaries Conference and School of Information.—The annual secretaries conference and school of information sponsored by the Michigan State Medical Society was held at the Book-Cadillac Hotel, Detroit, January 28. Among the speakers were:

- Dr. William W. Bauer, Chicago, Director, Bureau of Health Education, American Medical Association, First Things First.
- John F. Hunt, Chicago, executive, Foot, Cone & Belding, The Selling Job of a Physician—What Must Be Done Now.
- Edward F. Slade, Chicago, administrator, National Physicians of Medical Service, The Program and Objectives of the Michigan Physicians Committee.
- Paul D. Bagwell, East Lansing, head, speech department, Michigan State College of Agriculture and Applied Science, Proposed Amendment to the Constitution of the State of Michigan.
- Dr. Joseph S. Lawrence, Washington, D. C., director, Washington Office, Council on Medical Service and Public Relations, American Medical Association, The Work of the Washington Office of the Council on Medical Service and Public Relations.
- Dr. Edward F. Slade, Traverse City, chairman of the council of the state society, Physical Rehabilitation Program of the Federal Government.

MINNESOTA

Personal.—The public library at Madelia has been presented with a number of books dedicated to the memory of Dr. William J. McCarthy. The donor was A. L. Sperry, Owatonna attorney, who was a lifelong friend of Dr. McCarthy.

Memorial to Dr. Ernest Meland.—A group of professional friends and former patients of the late Dr. Ernest L. Meland are contributing to a fund to create a memorial in his honor, which will probably take the form of a fellowship or research project in urology at the University of Minnesota Medical School, Minneapolis. A temporary committee is in charge of collecting the fund and will turn the money over to the Minnesota Medical Foundation, a perpetual, charity trust, with the recommendation for the end to which it might be used. The project is not sponsored by the Hennepin County Medical Society but represents a desire on the part of personal friends and former patients to create a memorial in his honor.

Physician Charged with Fraudulent Prescription Writing.—On January 16 Dr. Joseph A. Duclos, Henderson, pleaded guilty at the U. S. District Court at Mankato to an indictment charging three violations of the Harrison Narcotic Law. In the first count the physician was charged with writing a fraudulent prescription for one Gust C. Lange, a member of the federal bureau of narcotics, the prescription calling for twenty $\frac{1}{4}$ grain morphine sulfate hypodermic tablets and being written for Lange under the name of Harold Erickson. The second count charged the physician with a similar violation and the third was selling one hundred $\frac{1}{4}$ grain morphine sulfate tablets to the same informer for the government for \$25. The defendant received a suspended sentence with the warning that any further violation of the narcotic law will result in a prison sentence.

MISSOURI

State Meeting Canceled.—The Missouri State Medical Association announces the cancellation of its meeting which was scheduled to be held in St. Louis, April 22-24.

MONTANA

Tularemia Occurs in Chipmunk.—The recovery of *Pasteurella tularensis* from a chipmunk, *Eutamias* sp., adds this rodent to the already long list of animals of native fauna in which tularemia occurs spontaneously. According to *Public Health Reports*, January 5, the chipmunk from which the isolation was made had been captured alive in June 1939 at a summer camp on Mica Bay, Lake Coeur d'Alene, Kootenai County, northern Idaho. It died two days later and the carcass was forwarded to the Rocky Mountain Laboratory, Hamilton. The isolation of the bacterium was from the heart ilton. The isolation of the bacterium was from the heart blood, taken just before death, of two guinea pigs which had been injected with a pooled suspension of spleen, liver and lung tissue.

NEW JERSEY

State Society Moves.—The executive and editorial offices of the Medical Society of New Jersey have been moved to the society's new home, 315 West State Street, Trenton (THE JOURNAL, Dec. 16, 1944, p. 1040).

Health Talks.—The Newark Museum opened a series of "Timely Talks on Health" January 11 with Dr. Benjamin I. Saslow, Newark, discussing "Nutrition in Wartime." Dr. Arthur J. Ellis, Newark, lectured January 18 on "Nervous and Mental Diseases in Military Personnel," Dr. Henry C. Barkhorn, Newark, January 25 on "Your Ear" and Dr. Ellis L. Smith, Belleville, February 1 on "Tropical Diseases."

NEW YORK

New Bureau of Medical Care Insurance.—The *New York State Journal of Medicine* announces the appointment of Mr. George P. Farrell, Buffalo, as director of the newly created bureau of medical care insurance of the state medical society. Mr. Farrell will have offices at 292 Madison Avenue, New York. The bureau will carry forward the practical business of the establishment on a broad base of prepaid medical care insurance in the state. Mr. Farrell had formerly served as enrolment supervisor of the Western New York Medical Plan, Inc., and the Western New York Hospital Service, Inc., Buffalo.

Women Physicians Oppose Chiropractic Bill.—The Women's Medical Society of New York, meeting in executive session February 3 at the New York Hospital, unanimously adopted a resolution opposing the chiropractic bill now before the state legislature as "detrimental to the health and welfare of the people of the state of New York." According to the *New York Times* the society's objections to the bill, which would license chiropractors in the state, were contained in a five point petition now being circulated among its members. It maintains that the bill, if passed, would permit unqualified persons to diagnose and treat illness and that the educational standards proposed are greatly inferior to those required of physicians and osteopaths.

Neuropsychiatric Clinic to Be Created at Rochester Medical School.—The establishment of a neuropsychiatric clinic at the University of Rochester School of Medicine and Dentistry, Rochester, has been made possible by a gift of securities to the university by Mrs. Helen W. Rivas of New York City and Le Roy, N. Y. Of the total gift a portion is designated for construction and equipment of a building to house the clinic as a unit of the School of Medicine and Dentistry and of Strong Memorial Hospital. A trust fund has been set up to operate and maintain the clinic. The new unit will be constructed as soon as can be practicable in view of present building conditions. In the meantime a committee of the medical school faculty will survey the field throughout the country to select a man to head the clinic so that he may participate in preparing the plans for the physical plant and the staff organization. It is contemplated that the clinic will be used for the study and care of persons having functional nervous disorders rather than for those with extreme mental ailments. Provision will be made for ample laboratory space for active research and investigation. It is planned to have beds for from 50 to 60 inpatients, and extensive use of the clinic for ambulatory patients is anticipated. Income from the endowment fund set up for the clinic will be paid to the university and accumulated to finance the project.

New York City

Volunteer Corps Organized for Cancer Work.—A new volunteer corps to help in the treatment of cancer patients, both at home and in hospitals, began training February 6 under a program that may be extended to other parts of the country, the *New York Times* recently reported. Known as Field Army nursing aides, the unit will take the Red Cross Home nursing course along with special lectures on cancer.

Public Health and the Doctors.—On February 7 the *New York Times* presented a forum on "Public Health and the Doctors," with Waldemar Kaempffert, science editor of the *Times*, as moderator. Among the participants were:

- Michael M. Davis, Ph.D., chairman, committee on research in medical economics, State of the Nation's Health.
- Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, Free Clinician and the Fee for Service System.
- Dr. Kingsley Roberts, director, medical administration service, Graduate Practice of Medicine on the Prepayment Plan.
- Hon. Claude Pepper, U. S. Senator from Florida, The Best Way of Meeting the Medical Needs of the Country by Legislation.

The Niles Memorial Lecture.—Dr. Edwin Cowles Andrus, associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore, and chief of the division of medicine committee on medical research, Office of Scientific Research and Development, gave the annual Walter L. Niles Memorial Lecture, February 20, at Cornell University Medical College on "Wartime Medical Research." The lecture is sponsored by Tau chapter of Nu Sigma Nu.

Friday Afternoon Lectures.—Subsequent lectures included in the Friday afternoon series at the New York Academy of Medicine, which opened November 3 (*THE JOURNAL*, Oct. 14, 1944, p. 445 and Dec. 23, 1944, p. 1095), are:

- Dr. Clyde Leroy Deming, New Haven, Hormonal Treatment of Prostatic Malignancy, March 2.
- Dr. Peter Vogel, Pathogenesis, Diagnosis and Treatment of Anemia of the Newborn, March 9.
- Dr. Nathan Rosenthal, Recent Advances in Laboratory Procedure, March 16.
- Dr. Marcy L. Sussman, Scope of Radiology in the Examination of the Upper Gastrointestinal Tract, March 23.
- Dr. A. Benson Cannon, Treatment of Syphilis with Penicillin, April 6.
- Dr. Ephraim Shorr, Recent Developments in Our Knowledge of the Metabolism of Bone in Health and Disease, April 13.
- Dr. Clifford B. Lull, Indications and Contraindications for Caudal Analgesia, April 20.

Forum for Research Workers.—The New York Academy of Medicine will hold a meeting on May 16 to provide a forum in which research workers of New York City and vicinity may present results of original research in clinical medicine. The meeting is being arranged by the committee on medical education of the academy in view of the few meetings of national medical societies before which research work has usually been presented. All research workers of greater New York and neighboring cities within a radius of 100 miles are invited to submit abstracts, not to exceed 200 words in length, of proposed presentations to the secretary of the committee on medical education of the New York Academy of Medicine, 2 East 103d Street, New York 29, not later than April 5.

Hospital Service Raises Age Limit.—Sixty-five instead of 60 has been established as the age limit for enrolment in the Associated Hospital Service of New York on an individual basis, it was announced on February 7. The age limit of 65 still remains in effect for persons who enroll in groups. In a statement to the press Mr. Louis H. Pink, president, stated, "Hospital use goes up rapidly with age and that is why some age limit is necessary. While it is more expensive to provide for older people it is desirable from the social point of view. Older people as a rule do not have the earning capacity of younger ones, and in normal times many are not employed at all. Their hospital needs are greater and their ability to pay is less. We cannot strain our resources to help aging people or be unfair to the public as a whole, but as far as possible we should provide for them. We never drop existing subscribers who continue their membership after 65 years of age, but some limitation is necessary for new subscribers. We are happy that we are able to raise our age limit to 65. Applicants must, of course, be in good health and meet the medical and physical requirements."

OHIO

Hospital Named for Dr. H. Kennon Dunham.—On February 6 the board of trustees of the Hamilton County Tuberculosis Hospital, Cincinnati, changed the name of the institution to the Dunham Hospital in honor of the late Dr. Henry Kennon Dunham, who served as medical director there from 1914 to 1941. After his resignation as medical director he was appointed a member of the board of trustees, serving until his death on April 27, 1944.

Roger Heering Becomes State Director of Health.—Roger E. Heering, Surgeon, U. S. Public Health Service, has been appointed state director of health, his term to run to Jan. 1, 1950. Dr. Heering succeeds Dr. Roll H. Markwith, Columbus, whose term expired Aug. 20, 1944. Mr. James E. Bauman, chief of the legal division in the department, has been acting director of health since Aug. 21, 1944 (*THE JOURNAL*, Oct. 7, 1944, p. 377). Dr. Heering has been assigned to the Ohio Department of Health since 1943 as venereal disease control officer. He served in a similar position for the city of Cincinnati from 1939 to 1941, when he became venereal disease consultant for the U. S. Public Health Service in a ten state area. Dr. Heering graduated at the University of Michigan Medical School, Ann Arbor, in 1933 and received a degree in public health from Johns Hopkins University in 1939. He was commissioned an assistant surgeon in the U. S. Public Health Service in 1934, being promoted in 1943 to surgeon.

SOUTH CAROLINA

State Society Approves Proposed Expansion of Medical School.—At a special meeting of the council of the South Carolina Medical Association recently approval was given to the proposed expansion program for the Medical College of the State of South Carolina, Charleston. The council went on record in offering its full support to the board of trustees of the college to attain this objective. The state institution proposes, among other things, to extend its clinical teaching facilities and to establish a clinical center for reference of problem cases from physicians throughout the state. A hospital included in the general setup would be not just a general hospital, it is pointed out, but would be a teaching, diagnostic and research clinic. The service would be on a statewide basis and not competitive with private practitioners or other hospitals. The patients would be referred by private physicians but would remain private patients of the doctors who sent them.

TENNESSEE

State Meeting Canceled.—The Tennessee State Medical Association announces the cancellation of its regular meeting, which was scheduled to be held April 10-12 in Nashville.

Personal.—A dinner was held at the Belle Meade Country Club, December 15, in honor of Dr. Barney Brooks, professor of surgery, Vanderbilt University School of Medicine, Nashville, who was celebrating his sixtieth birthday.—Dr. Francis H. Cole, director of the tuberculosis control division of the Memphis and Shelby County Health Department, has been given a two year leave of absence. He will go to New York City for a postgraduate training course in thoracic surgery at Bellevue Hospital.

Consolidated Medical Assembly of West Tennessee.—A new medical society has been set up in the state to be known as the Consolidated Medical Assembly of West Tennessee. The idea to form the new unit stemmed from a suggestion of Dr. Stanford M. Herron, Jackson, secretary of the Madison County Medical Society, and on Dec. 5, 1944 a number of physicians met at Jackson from the counties of Madison, Chester, Henderson, McNairy, Fayette, Carroll, Hardeman, Crockett, Benton, Decatur, Haywood and Gibson to discuss the proposed new organization. Officers of the new group, which will have a membership of about 106, include Drs. Ernest M. Smith, Selmer, president; John W. Morris, Somerville, Cornelia J. Huntsman, Lexington, and Roy M. Lanier, Brownsville, vice presidents, and Dr. Herron, secretary and treasurer.

TEXAS

Clinical Conference Canceled.—The Dallas Southern Clinical Society has voluntarily canceled its spring clinical conference scheduled for Dallas, March 19-22.

Memorial to Physician.—A lounge in the Truett Memorial Building of Baylor University Hospital, Dallas (*THE JOURNAL*, Dec. 16, 1944, p. 1041), will be furnished as a memorial to Dr. Benjamin H. Freeman, Garland, as the result of a gift by Mrs. Freeman, Garland, and her daughter, Mrs. Charles Dent, Dallas.

Grants for Research.—Eli Lilly and Company recently made a grant of \$2,500 to Dr. Donald Slaughter, dean of students, Southwestern Medical College of the Southwestern Medical Foundation, Dallas, for the study of aspergillic acid and other antibiotics in the department of pharmacology by Andres Goth, assistant professor of pharmacology. The Rose Lampert Graff Foundation, Los Angeles, recently made a grant of \$500 to Simon Edward Sulkin, Ph.D., associate professor of bacteriology and immunology at the school for studies on neutrotropic viruses.

GENERAL

Alcohol Hygiene Bulletin.—*Alcohol Hygiene* is the publication of the recently created National Committee on Alcohol Hygiene. It will be published bimonthly for the committee by Alcoholism Publications, 2030 Park Avenue, Baltimore 17.

Film on Rheumatic Fever.—"Jimmy Beats Rheumatic Fever," a fifteen minute sound film strip, has just been released by the Metropolitan Life Insurance Company. It was made under the supervision of Dr. George M. Wheatley, New York, assistant medical director of the company, and the script was reviewed by Dr. T. Duckett Jones, Boston. Requests for the use of the film should be addressed to the welfare division, Metropolitan Life Insurance Company, 1 Madison Avenue, New York 10.

Meetings Canceled.—The council of the American Association of Pathologists and Bacteriologists voted unanimously to cancel scientific meetings for the year 1945. Proposals for membership will be voted on by the council at a meeting to

be held in the late spring. They should be in the hands of the secretary, Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, not later than April 1. Members may notify the secretary of any other business which they wish to present to the council.—The American Urological Association, which was to hold its annual meeting at the Claridge Hotel, Atlantic City, N. J., June 11-14, has canceled its session.—The annual meeting of the American Society for Research in Psychosomatic Problems, which was to be held June 15-16 in New York, was canceled.

Efforts to Combat Rheumatic Fever.—Dr. Betty Huse, assistant director of the crippled children's program of the U. S. Children's Bureau, recently stated that efforts of nineteen states to combat rheumatic fever are "barely a drop in the bucket" but have given enough experience to serve as a basis for a future national program. School surveys indicate that a half million children have rheumatic fever, it is reported. According to Dr. Huse in the *New York Times*, among children from 5 to 14 years of age in 1942, the last analyzed year, 1,610 deaths were caused by rheumatic fever, as against 1,441 by pneumonia and 1,112 by tuberculosis, the two next highest causes of death. In the 15 to 19 age group 1,374 deaths were caused by rheumatic fever; more deaths, 2,967, were caused by tuberculosis; fewer, 917, by pneumonia. At the present time, it was stated, only 240 of the 3,082 counties in the United States and its possessions have some services available for children with rheumatic fever. Eight states, however, considered the work so important that a program was launched in wartime. The states were Missouri, Montana, Minnesota, Nebraska, South Carolina, Wisconsin, Michigan and Idaho. New York started the program and later discontinued it because of difficulties in getting personnel, it was stated.

The Pediatric Foundation.—The *Bulletin of the Pediatric Foundation* made its appearance with the December issue and discusses the organization of the foundation, chartered March 31, 1944 as a nonprofit membership corporation to encourage greater use of established work for mental and physical health in early childhood. The bulletin states that the foundation will devote its initial effort to two major objectives:

To aid in the provision of additional facilities, such as clinics, schools and camps, for the care, treatment and education of child victims of cerebral palsy, an affliction second only to infantile paralysis as a cause of crippling conditions among children.

To aid in the provision of additional centers and other facilities for the care, treatment and special education of child victims of rheumatic fever and to maintain a demonstration center for the convalescent care of such child sufferers, which has been in operation for the last four summers at East Hampton, Long Island, N. Y.

The new organization is said to be concerned exclusively with fields of service in which needed facilities have not yet been adequately provided, but at present its major concern is to stimulate the provision of such facilities for the care, treatment and education of child victims of cerebral palsy and rheumatic fever. The foundation plans to launch certain original projects but will be equally interested in encouraging greater use by physicians and parents of existing facilities of proved worth, not duplicating or competing with agencies or institutions already established but rather influencing the expansion of such services. The foundation, which will maintain offices at 12 East 41st Street, New York 17, will be managed by a board of directors consisting of ten members and an advisory committee of ten members. Mr. Arthur Dunn is counsel of the organization, Mary E. Collins assistant secretary, assistant treasurer and Mr. Bart Andress the executive vice president.

Edward Stitt Awarded Medal in Tropical Medicine.—A gold medal and an honorarium of \$500 for outstanding service in the field of tropical medicine were presented February 5 by the American Foundation for Tropical Medicine to Rear Admiral Edward R. Stitt (MC), retired, formerly Surgeon General of the U. S. Navy. The presentation was made on behalf of the foundation by Col. Richard Pearson Strong, M. C., director of tropical medicine at the Army Medical School, Washington, D. C., last year's recipient of the award and the person for whom the medal was named. The medal and honorarium were established in 1944 by the Winthrop Chemical Company (*THE JOURNAL*, March 4, 1944, p. 660). Known as the Richard Pearson Strong Medal and bearing a profile of Colonel Strong on its face, it is to be awarded annually for distinguished service in tropical medicine. In conferring the award Colonel Strong declared that "Admiral Stitt is an exponent of scientific truth in his medical publications and reviews. His leadership, inspiring example and devotion to work in the field of tropical medicine through many years have justly won for him the epithet of 'Father of Tropical Medicine in the United States.'" Admiral Stitt

graduated at the University of Pennsylvania Department of Medicine, Philadelphia, in 1889. In 1913 he wrote the first American textbook of tropical medicine. Among other positions held by Admiral Stitt are those of Surgeon General of the U. S. Navy from 1920 to 1928 and professorships in the schools of tropical medicine at Georgetown University, George Washington University and the University of the Philippines. The principal speaker at the presentation meeting at the University Club, New York, was Major Gen. George C. Dunham, M. C., of the Office of the Coordinator of Inter-American Affairs, who spoke on "Tropical Medicine and International Relations."

Educational Campaign on Epilepsy.—The recent distribution of a pamphlet on "Epilepsy—The Ghost is Out of the Closet" is one of the first ventures in an educational campaign to disseminate knowledge in this field. The Association to Control Epilepsy, 22 East 67th Street, New York 21, and the American Epilepsy League, 50 State Street, Boston, are jointly sponsoring the campaign. The former group was chartered under the University of the State of New York, Education Department, by the board of regents, April 21, 1944, and officers include Mr. David G. Baird, president, Dr. Tracy J. Putnam, vice president, Mr. Spencer B. Witty, treasurer, and Mrs. Henry H. Denning, executive secretary. The pamphlet is being distributed to teachers and school administrators, doctors, nurses, social workers, rehabilitation workers, civic educational and religious groups and employers of organized labor, and to individuals on request to the Public Affairs Committee, Inc., 30 Rockefeller Center, New York 20. The Association to Control Epilepsy is also sponsoring the Baird Foundation Clinic of Beth David Hospital, New York, which was established Aug. 1, 1944 primarily for the study, treatment and guidance of children with epilepsy and is said to be the only clinic which combines medical, psychologic and social treatment of persons with epilepsy. Another activity of the Association to Control Epilepsy is an attempt to reach industry through a general educational campaign and direct contact with the employer. A brochure is now being prepared clarifying the laws which concern the epileptic with regard to employment. In addition, the group's program includes a summer camp for epileptic and nonepileptic children, and plans are now under way to send 75 children to a camp in the Adirondacks from July 2 to August 27. The association also sponsors a private school where a child may be placed to aid in his permanent adjustment, and a directory of physicians, clinics and schools throughout the United States interested in the problem is now being compiled. The American Epilepsy League was founded in 1939.

Teaching Program for Leprologists.—For the last two years the Leonard Wood Memorial has cooperated with the Office of the Coordinator of Inter-American Affairs in providing a year's teaching program to leprologists from South America and Mexico. The first group included Drs. Alberto Caballero V., Colombia; Eduardo Alberto Carboni, Argentina; Rafael Cepeda R., Colombia; Artur Porto Marques, Brazil; Augusto Rodolfo Mercu, Argentina; Roberto Numez Andrade, Mexico; Luis Rendon Ch., Ecuador, and Glynn Leite Rocha, Brazil. The second group is composed of Drs. Rubem David Azulay, Brazil; Luiz Marino Bechelli, Brazil; Jose de Jesus Castaneda, Mexico; Jacinto Convit, Venezuela; Wallace Cranford, Canada and China; R. Ben Gullison, Canada and India; Antonio Jasbon-Mantilla, Colombia, and Jorge Suarez, Bolivia.

The School of English at the University of Michigan, Ann Arbor, had a three months course at the Medical School and Hospital, Columbia University, New York, in dermatology and is now at Western Reserve University School of Medicine, Cleveland, for a three months course in epidemiology and pathology. Completing their work at Western Reserve, they will go to the U. S. Marine Hospital (National Leprosarium) at Carville, La., where they will finish their training with two months of work in the clinics. The Office of the Coordinator is responsible for the expenses of these men, and the Leonard Wood Memorial was responsible for their selection and training. The selection was made as a result of a visit to South American countries by Malcolm H. Soule, Sc.D., of the University of Michigan, Ann Arbor, present chairman of the medical advisory board of the Leonard Wood Memorial, who recommended candidates to the medical board. This group made the final selection. According to Perry Burgess, LL.D., New York, president of the Leonard Wood Memorial, the results of the program have been most satisfactory. The memorial, which presents the students with a certificate of their studies on their completion, restricted the candidates to graduate physicians engaged in antileprosy work.

Reform of Psychiatric Services

Speaking at the centenary luncheon of the Royal Medico-Psychological Association, the minister of health, Mr. Willink, predicted important reforms in psychiatric services. Among these was unified control of all mental health services under a single set of authorities. In every area there should be a single body to deal with all aspects of mental health, the minister stated, so that they could survey the field as a whole, instead of a variety of authorities or combination of authorities, each concentrating on a limited section of the entire field. Unified control was held essential to the proper development of a comprehensive outpatient service, the first great step toward application of the principles of preventive medicine to mental health. There must be a parallel development of the ancillary services, Mr. Willink added, for it is uneconomical to leave a highly trained psychiatrist to work as best he can without the knowledge of the patient's home and occupational background which a trained social worker can give him. It is even more wasteful to leave a psychiatrist in charge of an outpatient center without adequate clerical assistance, he said.

Psychiatry is still a young specialty and has suffered from the relative isolation of many mental hospitals and the difficulty which the medical staffs have keeping in touch with general medicine, the speaker declared. He was anxious to secure a closer relation between mental and general hospitals, he said, not only by interchange of staffs but by establishing psychiatric units in all the hospitals. The report of the Royal College of Physicians on medical education suggested that every teaching hospital should have a psychiatric department which should form a link with a mental hospital, he pointed out.

Another important task would be the development of a more scientific system of training psychiatrists, it was held. The time has gone by when young medical officers should be left to train themselves, the minister believes. Psychiatry has suffered from being split into too many sections; in the postgraduate training of the future a broader view should be taken and mental deficiency and child psychiatry should be included, he stated. All mental hospitals should take part in a well planned scheme of research, he said in conclusion.

The Friends' Ambulance Unit

The principles of the Society of Friends prevent members from fighting in war, but they have distinguished themselves by their ambulance work and relief measures. The December *Bulletin of the Friends' Ambulance Unit* says seven teams are now working in the Netherlands under the direction of the civil affairs branch of the army. They receive and register refugees, help with medical examination and treatment, provide bedding and sleeping rooms, organize catering arrangements and volunteers among the refugees and attend to their personal problems. They established a communal kitchen to supply meals on an emergency basis and converted a large concentration camp into a transit center for refugees. They also helped to organize survey parties to investigate conditions in Normandy. These surveys revealed widespread dysentery, scabies and impetigo. Inmates of the former hospice at Falaise were living in byres, as no beds were available. Patients with tuberculosis were lying on straw, and the only persons caring for them were a priest and three or four sisters, it was found.

Mobile surgical teams maintained on the Yunnan front in China have contributed to raising standards of medical service, which are now regarded as the best since the war began.

Tenching is the largest city retaken by the Chinese. The arrival of the Japanese drove out 75 per cent of the population. Its recovery, against which the Japanese fought to the last man, reduced it to complete ruin. Corpses of men and horses lay in shallow graves and produced a horrible stench. Vultures circling over the city were gorged. Now the surgical teams of Friends in cooperation with the Chinese Red Cross maintain a hospital and a clinic and do public health work which is regarded as a model for the future.

Research on Filariasis

Two scientists from the research staff of Columbia University, New York, have been working in San Juan since January 5 in connection with a major experiment on the strange tropical disease filariasis in which more than 25 island patients, including children, have been undergoing special treatment since early last summer. These investigators, James T. Culbertson and Harry Rose, decline to comment on what success has been obtained with their experiment, which is believed to be one of the largest of its kind undertaken during the war, but some light was shed on their work by a Universal Trade Press Syndicate correspondent.

Drug refinements over established technics were placed in use early last summer after the two men had come to San Juan to supervise the selection of patients and the beginnings of treatment. The two scientists then returned to New York and a steady stream of blood samples were sent to them for study during the months preceding their return to San Juan. After approximately six months of analysis they returned to San Juan on January 5. Part of the experimental treatment was said to consist of administration of comparatively new derivatives of antimony. At about the same time other New York scientists were studying what was reported to be encouraging results obtained in the treatment of filariasis with another antimony derivative, anthiomaline. Research had been done with this drug at St. Croix, Virgin Islands, and it was described by doctors here as a big stride toward a cure of the disease. Probably the most spectacular of all tropical diseases, filariasis, which in the advanced stage results in elephantiasis, has rarely been cured heretofore. The return of some war veterans from tropical battle areas with the disease accentuated the almost insignificant medical problem that the disease formerly created in the United States. In Puerto Rico the affliction, while not a major medical problem, is described by health officials as fairly prevalent.

Pan American Public Health Meeting in Puerto Rico

All Latin American nations have been invited to attend a conference of the Puerto Rico Public Health Association to be held at the School of Tropical Medicine in San Juan, February 14-17, according to Dr. Guillermo Arbona, secretary of the organization. Sessions at the school, which are to be held primarily on the subject of public health and sanitation, will be bilingual. Papers read in Spanish will be summarized in English, and vice versa. The British government may be represented. Sir Rupert Biercliff of the British West Indies Office of Development and Welfare has been invited and has said he may come. At least one woman scientist is also expected to be present. Dr. Dorothy B. Nyswander, consultant on health education of the Office of Inter-American Affairs, has announced her intention to attend. In addition to the representatives of other American nations, delegates of the sanitary bureau of the Pan American Union and representatives of the Coordinator of Inter-American Affairs and the United States Public Health Service are expected to attend.

Study of Coronary Sclerosis

Dr. Reinaldo Chiaverini and Dr. Paulo Rebocho of the Department of Medicine of the University of São Paulo have just published the results of a clinical and pathologic study of coronary sclerosis. For this study they used records of 1,083 necropsies performed during the year 1942 in the department of pathology of the university. Of this total, made up of persons of both sexes from 1 year of age up to 90 years, they found 292 (24.2 per cent) typical cases of coronary sclerosis as shown by macroscopic examination alone. There were no cases in the group 0-19 years, 6 cases (3.5 per cent of the total number in this age group) in the group 20-29 years, 17 cases (10.4 per cent) in the group 30-39 years, 54 cases (33.9 per cent) in the group 40-49 years, 62 cases (48.0 per cent) in the group 50-59 years, 53 cases (63.1 per cent) in the group 60-69 years and 70 cases (83.3 per cent) in the group 70 years and over. The mean age at death for the whole group of 262 cases was 59.5 years. Coronary sclerosis was present in 26.4 per cent of the males and 19.8 per cent of the females. The mean age of the men was 61.5 years and that of the women was 58.8. The condition was found in 27.4 per cent of white people and 18.9 of the colored. Coronary sclerosis was more frequent in foreigners (52.0 per cent) than in native Brazilians (35.5 per cent), taking into consideration only those more than 30 years of age. Brazilians are shown to fall victims to coronary sclerosis at an earlier age than are foreigners, as the mean age at death was 53.4 years for the former and 62.1 for the latter. Coronary sclerosis evolved into cardiac insufficiency in 49.6 per cent of the cases studied; it ended in myocardial infarction in 8.4 per cent of the cases; in 25.6 per cent of the cases there was hypertrophy of the left ventricle (probably through chronic arterial hypertension). In a total of 80.9 per cent of the cases there was coexistent aortic arteriosclerosis. Coronary sclerosis remained absolutely asymptomatic during the whole life of the patient (latent coronary arteriosclerosis) in some cases. In other instances it gave rise to one or more clinical manifestations, such as congestive cardiac insufficiency, angina pectoris, electrocardiographic changes or infarct of the myocardium.

In each of the 88 patients on whom electrocardiographic examination was performed the electric curve revealed some change. The electric axis was displaced to the left in 60 cases, to the right in 5 and was not displaced in 23. Sinus rhythm was present in 73, auricular fibrillation in 15 and ventricular extrasystole in 19, partial auriculoventricular block in 1, branch block in 13 and lesser QRS changes in 61 cases. In the majority of cases there were T or ST segment changes. In 10 cases there was a P change. The Wassermann reaction was positive in 25 out of 78 patients on whom the test was made. Hypertension of the peripheral circulation was coexistent in 62 cases, in 10 there was cardiovascular syphilis, in 2 cardioarticular rheumatism, in 6 chronic pulmonary cardiopathy and in 1 chronic myocarditis from Chagas disease.

Purification of Vaccine Pulp by Mixture of Glycerin and Penicillin

Dr. Cassio Miranda of the Oswaldo Cruz Institute has published a preliminary note to report the good results of his experiments to improve the purification of cowpox vaccine pulp through the addition of penicillin to the glycerin routinely used for exterminating pathogenic bacteria. This new technic may contribute toward solving a problem of first importance, as the complete purification of the immunizing material commonly used to vaccinate against smallpox is yet somewhat incomplete and defective. It is well known that glycerin is the universal purifying material because of its differential germi-

cide properties, which may be employed almost without harmful effect on the immunizing virus. But, as glycerin has a lesser bactericidal action on cocci than, on the other hand, are particularly sensitive to penicillin, Dr. Miranda thought it would be a good idea to associate this drug with glycerin in order to improve the purification. He used a solution of penicillin prepared at the Oswaldo Cruz Institute and containing 25 Oxford units per cubic centimeter. He mixed and finely ground the cowpox pulp taken from 5 different calves and put 5 cc. of such ground pulp in three glass tubes, each containing a distinct purifying material: in the first tube 5 cc. of ground pulp plus 5 cc. of sterilized glycerin, in the second tube 5 cc. of pulp plus 5 cc. of penicillin solution and in the third tube 5 cc. of pulp plus 5 cc. of a mixture of 50 per cent penicillin solution and 50 per cent sterilized glycerin. After having been well shaken, the three tubes remained twenty-four hours at room temperature and then were kept in the refrigerator at 6-8 C. After four days each mixture was plated on plain agar (0.1 cc. of material in each plate) and incubated at 37 C. for forty-eight hours. The plates with pulp plus glycerin showed many large colonies, white and yellow, of *Staphylococcus albus* and *aureus*; the plates with pulp plus penicillin showed many small, transparent colonies; the plates with pulp plus the mixture of penicillin and glycerin showed many colonies of both the transparent and the colored types. The plating of material kept for two, six, eight or more days in the refrigerator showed a progressive reduction in the number of colonies. After thirty days in the refrigerator the material was tested on rabbits for its immunizing capacity, giving the same results with the three kinds of mixture. A second series of mixtures—pulp plus glycerin and pulp plus penicillin—kept for thirty days in the refrigerator showed complete absence of bacillary forms and the presence of 6,080 colonies of *Staphylococcus albus* and *aureus* in the former mixture, while the latter presented only a thin, transparent film of a pure cultured, gram negative bacillus, probably *Escherichia coli*.

Dr. Miranda is still experimenting with many more details of the technic, the results of which will be reported later but from the present beneficial effects he believes that the mixture of glycerin and penicillin may be of real value in improving the preparation of smallpox vaccine.

Marriages

NEWTON WEBSTER ALLEBACH, Charleston, W. Va., to Miss Rosemary Jamison of Gloucestershire, England, in New York, December 23.

ROBERT HILTON STEPHENSON, Brantley, Ala., to Miss Emily Thornton Clark at Long Beach, Calif., November 3.

HENRY BOWLING TURNER, Memphis, Tenn., to Miss Anne Rodgers Doughten in Philadelphia, January 16.

CYRIL JOHNSTONE JONES, New York, to Miss Rose Victoria Randolph at Dorchester, Mass., September 25.

JOHN McLEAN WILSON, Darlington, S. C., to Miss Amelia Talbert of Greenwood in Greenville recently.

JOHN L. JACKSON III, Wichita Falls, Texas, to Miss Frances Harris Lockhart of Galveston, November 29.

WILLIAM ROBERT KUEFFNER JR., St. Paul, to Miss Elizabeth Hunter Berg of New York, January 22.

BRYAN VICTOR WILLIAMS, Pittsburgh, to Miss Jean Louise Davis in Oceanside, Calif., December 2.

JOHN M. DODD JR. to Miss Gladys Crawford, both of Ashland, Wis., at Seattle, January 20.

WILLIAM C. OWENS, Baltimore, to DR. ELLA M. UHLEP of Allentown, Pa., December 27.

PHILIP R. ROEN, New York, to Miss Florence S. Glickstein of Brooklyn, December 23.

PHILIP F. NEWMAN to Mrs. Rebecca Snyder, both of Allentown, Pa., December 31.

Deaths

Fred Houdlett Albee Ⓒ noted orthopedic surgeon, died in New York February 15, aged 68.

Dr. Albee was born in Alna, Maine, April 13, 1876. He studied at the Lincoln Academy, receiving his A.B. degree at Bowdoin College in 1899 and his M.D. at Harvard Medical School in 1903. He studied extensively throughout Europe and during his career received numerous honorary degrees and citations in recognition of his contributions to the field of orthopedic surgery, in which he was a pioneer and in which he had devised new technics. He had served as professor and director of the department of orthopedic surgery at the New York Post-Graduate Medical School, Columbia University, and as professor at the University of Vermont College of Medicine, holding honorary professorships at the University of San Marcos, Lima, Peru, and the College of Physicians and Surgeons, Atlanta, Ga. He had been consulting surgeon to various hospitals, to the Pennsylvania Railroad System and Seaboard Air Line, consultant in orthopedics to the Byrd Antarctic Expedition and member of the advisory orthopedic council to the Surgeon General of the U. S. Army.

Dr. Albee was a member of scientific groups in both the United States and countries throughout the world. He was a life member of the American College of Surgeons, once serving as a member of its board of governors, founder of the International Society of Orthopedic Surgeons and formerly president of the Association of Surgeons of the Pennsylvania Railroad, American Orthopaedic Association, American Academy of Orthopaedic Surgeons, Pan American Medical Association and the International College of Surgeons, and he had been certified by the American Board of Orthopaedic Surgery. He had been a member of President Hoover's Conference in Child Health and Protection.

During World War I he held the rank of colonel in the Medical Reserve Corps, serving as chief of staff of General Hospital number 3 at Colonia, N. J., a unit which he helped establish and which, as the result of the work done there, became the first rehabilitation center, later evolving into the various facilities of the New Jersey Rehabilitation Commission. In 1940, for his twenty years' service as chairman of this commission, he was honored with a testimonial dinner sponsored by the state department of labor and rehabilitation. He had demonstrated original surgical methods of bone grafting in Germany, England and France in 1914 and in the military hospitals of France in 1916. He was the official representative of the Medical Corps of the U. S. Army to the Inter-Allied Congress in Rome, Paris and Bologna in 1919 and of the U. S. Army at the Netherland Orthopedic Congress in Amsterdam in 1923. He was the honorary American president of the International Congress for Industrial Accidents and Diseases in Amsterdam in 1925 and in Budapest in 1927 and, in 1933, founder of the Florida Medical Center, Venice.

Among Dr. Albee's prolific contributions to the literature are Bone Graft Surgery, 1915, Orthopedic and Reconstructional Surgery, 1919, Injuries and Diseases of the Hip, 1927, Bone Graft Surgery in Disease, Injury and Deformity, 1940, and a Surgeon's Fight to Rebuild Men, 1943.

Robert Tuttle Morris Ⓒ prominent for his contributions to the specialties of gynecology and surgery, died at the Stamford Hospital, Stamford, Conn., January 9, aged 87, of cerebral thrombosis and generalized arteriosclerosis.

Dr. Morris was born in Seymour, Conn., May 14, 1857. He studied at Cornell University from 1876 to 1879, taking his M.D. degree at the Columbia University College of Physicians and Surgeons in 1882. In 1891 he was given an honorary A.M. by Centre College in Kentucky. Dr. Morris evinced an early interest in surgery, going to London to observe Lister's technic. From 1899 to 1917, when he became emeritus, Dr. Morris was professor of surgery at the New York Post-Graduate Medical School, where he had earlier served as adjunct professor of surgery and instructor in clinical surgery. He devised many new surgical technics, creating one in operations for appendicitis which now bears his name. Garrison's History of Medicine credits Dr. Morris with many technical improvements and original ideas.

Dr. Morris held membership in a number of scientific societies, serving as president in 1907 of the American Association of Obstetricians and Gynecologists and in 1916 of the American Therapeutic Association, and for many years of the Physicians Home, Inc. He was a fellow of the American College of Surgeons.

Dr. Morris had written extensively, including "How We Treat Wounds Today," "Lectures on Appendicitis," "Hopkins's

Pond," "Dawn of the Fourth Era in Surgery," "Tomorrow's Topics Series," "Microbes and Men," "A Surgeon's Philosophy," "Doctors versus Folks," "The Way Out of War," "Nut Growing" and "Editorial Silence." His monographs and volumes dealt with practically all subjects, from early geological formations to the United States Senate.

After his retirement from active practice in 1917 Dr. Morris devoted most of his time to the philosophy of the naturalist, growing nut trees, planting twenty-six varieties of chestnuts, and observing birds and animals.

William Newbold Bispham Ⓒ Colonel, U. S. Army, retired, Baltimore; University of Maryland School of Medicine, Baltimore, 1897; lecturer in medicine at his alma mater; associate member of the Medical and Chirurgical Faculty of Medicine; veteran of the Spanish-American War and World War I; entered the medical corps of the U. S. Army as an assistant surgeon in 1900; became a captain in 1905, major in 1909, lieutenant colonel in 1917 and colonel in 1926; had been with the Militia Bureau from 1928 to 1932; assigned to the headquarters of the American Medical Association as liaison officer, Surgeon General's Office, U. S. Army, during World War I; fellow and for many years a member of the board of governors of the American College of Surgeons; member of the American Association of Tropical Medicine, the National Malaria Committee and the Baltimore City Medical Society; author of the recently published book, "Malaria"; wrote the Training Volume of the history of the Medical Department of the United States Army in the World War; died in the University Hospital January 1, aged 69, of cardiac decompensation, diverticulitis and renal failure.

John Quincy Myers Ⓒ Charlotte, N. C.; North Carolina Medical College, Davidson, 1904; member of the House of Delegates of the American Medical Association in 1920 and 1921, 1937, 1938 and 1939; past president of the Medical Society of the State of North Carolina and the Mecklenburg County Medical Society; formerly member of the state board of medical examiners; served as president of the North Carolina Board of U. S. Pension Examiners; organizer and first secretary-treasurer of the North Carolina Hospital Association; member of the draft board of Charlotte during World War I; founder and at one time owner of the Tranquil Park Sanitarium; medical referee of the Life Extension Institute, Metropolitan Life Insurance Company and the North Western Life Insurance Company; chairman of the Charlotte Medical Committee, Procurement and Assignment Service and the U. S. Manpower Commission since 1942; died December 3, aged 67, of coronary thrombosis.

John William Flinn Ⓒ Prescott, Ariz.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1895; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the House of Delegates of the American Medical Association from 1920 to 1922; past president of the Arizona State Medical Association; member of the National Tuberculosis Association; member of the school board, and president of the board of directors of the Hassayampa Hotel; president of the chamber of commerce, 1912-1913; at one time member of the board of regents of the University of Arizona; medical director and owner of the Pamsetgaaf Sanatorium; president of the Prescott Community Hospital staff; received an honorary M.A. degree from the University of Arizona in 1921; died November 21, aged 74, of carcinoma of the rectum.

Aaron Brown Ⓒ New York; Cornell University Medical College, New York, 1906; assistant clinical professor of medicine at the New York University College of Medicine; specialist certified by the American Board of Internal Medicine; member of the American Association for the Study of Allergy and the Society for the Study of Asthma and Allied Conditions; founder and once president of the Phi Delta Epsilon Fraternity; served as medical inspector for the city board of health; assistant visiting physician, Bellevue Hospital; attending immunologist, Midtown Hospital, and consulting physician to the Bronx Hospital; died January 24, aged 60, of coronary thrombosis.

Walter E. Bartlett, Elkton, Ky.; University of Nashville (Tenn.) Medical Department, 1896; member of the American Medical Association; died in Clarksville, Texas, November 11, aged 82.

Julia Mary Lewandowski Bauman Ⓒ Holyoke, Mass.; Woman's Medical College of Pennsylvania, Philadelphia, 1911; died November 17, aged 62.

Edwin Hamilton Bidwell, Niles, Mich.; Dartmouth Medical School, Hanover, N. H., 1884; on the staff of the Pawating Hospital; died November 13, aged 84.

Charles Robert Blake • Richmond, Calif.; Medical Department of the University of California, San Francisco, 1891; for thirty-four years health officer of Richmond; member of the honorary staff of the Richmond Hospital, where he died December 27, aged 76, of chronic nephritis and uremia.

B. Ray Browning, Littleton, N. C.; University of Maryland School of Medicine, Baltimore, 1891; local surgeon for the Seaboard Airline Railway; died November 26, aged 77, of cardiorenal vascular disease.

William Earl Bryan • Chattanooga, Tenn.; University of Tennessee College of Medicine, Memphis, 1917; served during World War I; past president of the Chattanooga and Hamilton County Medical Society; on the staff of the Erlanger Hospital; died December 29, aged 58.

John A. Cameron, Pickford, Mich.; Detroit College of Medicine, 1896; also a pharmacist; died in Miami Beach, Fla., December 17, aged 78, of cerebral hemorrhage.

Victor Alvin Carriere, St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1896; died in Clayton December 18, aged 71, of coronary occlusion.

William Wright Christian, St. Paul; New York Homeopathic Medical College and Hospital, New York, 1895; died in the Ancker Hospital November 4, aged 75, of hypertensive heart disease and myocardial infarction.

Christopher Columbus Cooke, Richmond, Va.; Howard University College of Medicine, Washington, D. C., 1921; served an internship at City Hospital number 2, in St. Louis; on the staff of the Richmond Community Hospital; died December 1, aged 60, of hypertensive heart disease.

Edward Moses Corbin, Sullivan, Ind.; Marion-Sims College of Medicine, St. Louis, 1899; member of the American Medical Association; honorary member of the Indiana State Medical Association; died December 12, aged 76, of coronary occlusion.

Allen Corson • Ocean City, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1907; past president of the Medical Society of Cape May County; in 1935 president of the New Jersey State Homeopathic Medical Society; on the staff of the Shore Memorial Hospital, Somers Point; died in Princeton December 25, aged 63, of cerebral hemorrhage.

Claud Burton Crawford, Blue Ridge, Ga.; Medical College of Alabama, Mobile, 1905; member of the American Medical Association; secretary of the Blue Ridge Medical Society; city physician; died November 7, aged 71, of uremia.

J. Seely Cummins, Warwick, N. Y.; the Hahnemann Medical College and Hospital, Chicago, 1891; for many years health officer of the village and town of Warwick; health officer of Greenwood Lake village; for fifteen years physician to the Orange County Farm; died December 10, aged 87, of arteriosclerosis.

Charles Tinsley Davis, Memphis, Tenn.; Vanderbilt University School of Medicine, Nashville, 1881; died November 27, aged 85, of chronic nephritis and uremia.

Isaac Alexander Dunlap, Sutherlin, Ore.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1899; at one time physician in charge of the Walla Walla Sanitarium, College Place, Wash.; died in the Portland Sanitarium, Portland, in November, aged 85, of coronary disease.

Robert George Feek, Au Sable Forks, N. Y.; Trinity Medical College, Toronto, Ont., Canada, 1891; for many years health officer of the town of Moira; died December 17, aged 88, of pernicious anemia.

James William Fleming, Utica, N. Y.; Albany Medical College, Albany, N. Y., 1908; member of the American Medical Association; school physician; on the staff of the Faxon Hospital; died January 21, aged 63, of heart disease.

Edgar Newton Fought, Philadelphia; Jefferson Medical College of Philadelphia, 1905; died in the Philadelphia General Hospital December 25, aged 67, of cardiovascular disease.

William F. Gardiner, San Diego, Calif.; Albany Medical College, 1883; died December 3, aged 87, of congestive heart disease.

Angelo David Garibotti, Santa Cruz, Calif.; Creighton University School of Medicine, Omaha, 1938; member of the American Medical Association; interned at the Creighton Memorial St. Joseph's Hospital in Omaha; on the staffs of the Santa Cruz Hospital, Santa Cruz County Hospital and the Sisters Hospital, where he died December 14, aged 32, of mushroom poisoning.

Luiz Rodrigues Gaspar, Honolulu, Hawaii, Université Libre de Bruxelles Faculté de Médecine, Belgium, 1897; died in Oakland, Calif., November 24, aged 70, of chronic interstitial nephritis and arteriosclerosis.

Samuel Gellert • New York; Columbia University College of Physicians and Surgeons, New York, 1904; member of the National Gastroenterological Association; on the staff of the City Hospital, Welfare Island; died November 2, aged 63, of lymphoma.

John Weaver Gordon • Clearfield, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; served an internship at the Presbyterian Hospital, Philadelphia; medical examiner of the draft board during World War I; fellow of the American College of Surgeons; head of the Swoope Maternity Unit, chief gynecologist and obstetrician, and president of the staff, Clearfield Memorial Hospital, where he died December 19, aged 66, of an embolism.

Samuel A. Greenberg • Forest Hills, N. Y.; Université de Lausanne Faculté de Médecine, Switzerland, 1941; interned at the Queen's General Hospital in Jamaica; died in the Jewish Hospital, Brooklyn, November 4, aged 28, of subacute endocarditis.

Jason Grant Hanks, Everett, Pa.; Jefferson Medical College of Philadelphia, 1890; member of the American Medical Association; president of the First National Bank; died in the Memorial Hospital, Cumberland, Md., December 14, aged 79, of arteriosclerosis and hypertrophy of the prostate.

Nelson Lewis Hansen, Emerson, Neb.; Sioux City (Iowa) College of Medicine, 1903; physician and surgeon for the Chicago, St. Paul, Minneapolis and Omaha Railroad; died November 26, aged 68, of Parkinson's disease.

John Hamilton Hansford, Pratt, W. Va.; University of Louisville (Ky.) Medical Department, 1888; member of the American Medical Association; honorary life member of the West Virginia State Medical Association; formerly on the staff of the Sheltering Arms Hospital and Training School for Nurses, Hansford; served as surgeon for the Chesapeake and Ohio Railway Company; died December 26, aged 80, of coronary thrombosis.

Chester Ellis Harris • Basin, Wyo.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; fellow of the American College of Surgeons; interned at the Michael Reese Hospital in Chicago; served in France as a captain in the medical corps of the U. S. Army during World War I; died December 21, aged 63, of coronary occlusion.

Edward Everett Hawes, Hyannis, Mass.; University of Vermont College of Medicine, Burlington, 1886; member of the American Medical Association; member of the senior staff of the Cape Cod Hospital, where he died November 30, aged 82, of arteriosclerosis and pneumonia.

Alfred Irwin Hayes, Denver; Colorado School of Medicine, Boulder, 1896; member of the American Medical Association; associate and honorary member of the Colorado State Medical Society; at one time mayor of Goldfield, Colo.; on the staff of the Presbyterian Hospital; died in St. Luke's Hospital November 25, aged 75, of spontaneous pneumothorax and myocarditis.

James Olin Horne Jr., St. George, S. C.; Medical College of the State of South Carolina, Charleston, 1943, under the Army Specialized Training Program and was commissioned a first lieutenant in the medical corps, Army of the United States; went on inactive duty in order to complete an internship and junior residency at the Medical Center of Jersey City; died December 8, aged 27, of lobar pneumonia.

Harry Lee Howell • Bloomington, Ill.; Rush Medical College, Chicago, 1904; county coroner; served during World War I; on the staffs of the Brokaw Hospital, Normal, and Mennonite Hospital; died December 16, aged 66, of emphysema.

William Thomas Huddleston, Konawa, Okla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1895; member of the American Medical Association; died November 30, aged 77, of heart disease.

Solomon L. Hull, Central City, Neb.; Rush Medical College, Chicago, 1889; died in Omaha October 3, aged 91, of bronchopneumonia.

John Davies Jackson • Danville, Ky.; College of Physicians and Surgeons of San Francisco, 1902; fellow of the American College of Surgeons; for many years physician and surgeon for the Kentucky School for the Deaf; for many years a member of the city board of education; on the staff of the Ephraim McDowell Memorial Hospital; local surgeon for the Louisville and Nashville Railroad; died December 13, aged 68, of coronary thrombosis.

Albertus Jeffers, Smith Center, Kan.; Kentucky School of Medicine, Louisville, 1907; served as president of the Smith County Medical Society; died December 3, aged 62, of cerebral hemorrhage.

Henry Jelen, Boston (licensed in Massachusetts by years of practice); died in the Memorial Hospital, Chelsea, Mass., December 13, aged 78, of coronary thrombosis.

Curtis C. Johnson @ Buffalo; University of Buffalo School of Medicine, 1920; attending obstetrician on the staff of the Millard Fillmore and Deaconess hospitals; died in Minot, N. D., December 22, aged 50, of coronary thrombosis.

William Barner Karstetter, Indianapolis; University of the City of New York Medical Department, New York, 1884; died December 2, aged 84, of arteriosclerosis.

Thomas Francis Kelly, New York; New York University Medical College, New York, 1897; member of the American Medical Association; served on the staffs of the New York, St. Vincent's and Roosevelt hospitals and the Vanderbilt Clinic; died November 15, aged 72, of acute cardiac dilatation.

Edward Vincent Killelea, Fitchburg, Mass.; Baltimore Medical College, 1903; died October 28, aged 63, of pulmonary tuberculosis.

Harry Jennings Knapp @ Newport, R. I.; Long Island College Hospital, Brooklyn, 1892; on the consulting staff and for many years an active member of the regular staff, Newport Hospital; died in the Roosevelt Hospital, New York, December 17, aged 74, of chronic myocarditis.

Frank John Kuta, Cleveland; University of Wooster Medical Department, Cleveland, 1907; died December 14, aged 69, of pneumonia.

John E. Lee, Venice, Ill.; Keokuk (Ia.) Medical College, 1902; member of the American Medical Association; for many years mayor of Venice; president of the First National Bank of Madison; died December 8, aged 69, of cerebral hemorrhage.

William Harvey Leffler @ Chicago; Chicago College of Medicine and Surgery, 1908; on the staff of the Lutheran Deaconess Hospital, where he died December 16, aged 69, of coronary occlusion.

Wiley Ernest Lindsay, Winchester, Tenn.; University of Tennessee Medical Department, Nashville, 1905; died December 13, aged 61, of cerebral hemorrhage.

Malcolm Robert Markson, Milwaukee; Chicago College of Medicine and Surgery, 1916; served during World War I; on the staff of the Veterans Administration Facility; died January 19, aged 58, of pneumonia.

Wayne Hamilton May @ Minneapolis; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1907; on the staff of St. Barnabas Hospital; died in a hospital at Hibbing, Minn., November 6, aged 67, of dissecting aneurysm.

Ralph Kleckner Mead, Chowchilla, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; served as surgeon for the Buffalo and Susquehanna Railway Company; died in the Peralta Hospital, Oakland, October 12, aged 65.

Louis Wesley Meckstroth @ Chicago; University of Minnesota College of Medicine and Surgery, Minneapolis, 1893; died December 12, aged 75, of coronary thrombosis.

John Morton Meloy, Greenfield, Ind.; Kentucky School of Medicine, Louisville, 1890; formerly medical officer at the Indiana Reformatory, Pendleton; died December 2, aged 82, of coronary thrombosis.

Madeline Ann Muldoon Melson @ Little Rock, Ark.; University of California Medical School, San Francisco, 1924; member of the American Academy of Pediatrics; interned at the University of California Hospital; formerly fellow in pediatrics at Mayo Foundation, Rochester, Minn.; served as secretary of the Arkansas State Pediatric Association; member of the attending staff of St. Vincent's Infirmary; died January 12, aged 47, of heart disease.

William Lucius Meng, Fergus Falls, Minn.; the Hahnemann Medical College and Hospital, Chicago, 1910; served overseas during World War I; on the staff of the Fergus Falls State Hospital; formerly on the staffs of the Veterans Administration facilities in Marion, Ind., and Perry Point, Md.; died in St. Luke's Hospital January 9, aged 64, of carcinoma of the rectum and liver.

William Daniel Mueller @ Lieutenant Colonel, U. S. Army, retired, Traverse City, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899; member of the American Psychiatric Association; served during World War I; entered the medical corps of the U. S. Army as a captain in 1920; promoted to major in 1929 and lieutenant colonel in 1937; retired Aug. 31, 1939; died in the Letterman General Hospital, San Francisco, Aug. 28, 1944, aged 68, of carcinoma of the pancreas.

George Stephen Munson, Albany, N. Y.; Albany Medical College, 1880; member of the American Medical Association; eye surgeon for the New York Central Railroad for more than fifty years; consulting oculist, St. Peter's Hospital; died December 9, aged 88, of injuries received when struck by an automobile in New York.

John William Neal, Monroe, N. C.; University of the City of New York Medical Department, New York, 1884; member of the American Medical Association; died in a Charlotte hospital November 10, aged 85.

William Northrup, Grand Rapids, Mich.; Western University Faculty of Medicine, London, Ont., Canada, 1894; member of the American Medical Association; served during World War I; fellow of the American College of Physicians; past president of the Kent County Medical Society; superintendent of the Michigan State Reformatory, Ionia; on the consulting staff of the Butterworth Hospital, St. Mary's Hospital and the Blodgett Memorial Hospital, where he died December 9, aged 77, of gangrenous appendicitis.

John Hamilton Nye, Cromwell, Ind.; Medical College of Indiana, Indianapolis, 1892; member of the American Medical Association; died January 9, aged 75, of cerebral hemorrhage.

Peter M. Ostrander, York, N. Y.; Homeopathic Hospital College, Cleveland, 1883; formerly health officer in Nunda and a member of the Rotary Club; died November 26, aged 92, of cerebral arteriosclerosis.

Joseph Barnes Palmer, Thomasville, Ga.; University of Georgia Medical Department, Augusta, 1904; member of the American Medical Association; on the staff of the John D. Archbold Memorial Hospital; died November 3, aged 67, of coronary thrombosis.

John C. Parrish @ Vandalia, Mo.; American Medical College, St. Louis, 1877; Marion Sims College of Medicine, St. Louis, 1891; member of the board of public works; local surgeon for the Alton Railroad for many years; died December 4, aged 90.

Robert J. Payne, Stafford, Va.; University College of Medicine, Richmond, 1899; member of the American Medical Association; past president of the Fredericksburg Medical Society; formerly mayor, member of the city council and chamber of commerce of Fredericksburg; died December 9, aged 71.

Daniel Edgar Pugh, Utica, N. Y.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1911; member of the American Medical Association; served overseas during World War I; examiner for the Veterans Bureau; formerly deputy health officer of the city of Utica; past president and secretary of the Medical Society of the County of Oneida; on the staff of St. Luke's Hospital; died January 11, aged 57, of cerebral hemorrhage following an automobile accident.

Jesse Baldwin Rutherford, Washington, D. C.; National University Medical Department, Washington, 1889; died in St. Elizabeths Hospital December 27, aged 87, of hypostatic pneumonia and arteriosclerotic heart disease.

James Joseph Ryan @ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1899; during World War I was chief medical officer of the Loyola Medical Unit at Camp Martin; from 1914 to 1924 professor of anatomy at Loyola University; on the staff of the New Orleans Eye, Ear, Nose and Throat Hospital from 1915 to 1917; senior surgeon on the staff of the Mercy Hospital and the Hotel Dieu, where he died November 24, aged 65, of hemiplegia and hypertension.

Guy W. L. Sandford, Madison Heights, Va.; University College of Medicine, Richmond, 1900; died November 6, aged 70, of angina pectoris.

Harry Louis Schultz @ Joliet, Ill.; Chicago College of Medicine and Surgery, 1917; since 1941 medical director of the Elwood Ordnance Plant; served during World War I; formerly on the staffs of Elmhurst Community Hospital, Elmhurst, Silver Cross Hospital, Joliet, and the Hospital of St. Anthony de Padua, Chicago; died December 17, aged 51, of coronary thrombosis.

Ford Wylis Sellars, East Milton, Mass.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1882; died January 3, aged 93, of pneumonia.

Howard Clay Sevier @ Tallulah, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1912; coroner of Madison Parish; died in the Mayo Clinic, Rochester, Minn., October 28, aged 55.

Arthur Louis Sherrill, Evanston, Ill.; New York University Medical College, New York, 1898; Cornell University Medical College, New York, 1899; assistant medical director

of the Equitable Life Assurance Company; died in St. Luke's Hospital, Chicago, December 2, aged 74, of generalized arteriosclerosis.

William K. Skilling, Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1911; member of the American Medical Association; director, bureau of child hygiene, city health department; died in the Union Memorial Hospital November 20, aged 59, of cerebral hemorrhage.

James Will Smith, Aurora, Mo.; Physio-Medical College of Indiana, Indianapolis, 1901; member of the American Medical Association; died December 4, aged 66, of coronary thrombosis.

Ralph Merle Smith ♂ Glendale, Calif.; College of Medical Evangelists, Los Angeles, 1916; fellow of the American College of Surgeons; instructor in surgery at his alma mater; served during World War I; formerly on the staffs of the Riverside Community Hospital, Riverside, Loma Linda Sanitarium and Hospital, Loma Linda, and the Riverside County Hospital, Arlington; surgeon on the staff of the Glendale Sanitarium and Hospital; died November 28, aged 57.

Roscoe Likes Smith, Los Angeles; John A. Creighton Medical College, Omaha, 1908; specialist certified by the American Board of Radiology, Inc.; at one time in charge of the department of radiology at the Lincoln General Hospital, Lincoln, Neb.; died November 7, aged 60.

Frederick Gaither Thayer, Medford, Ore.; Northwestern University Medical School, Chicago, 1907; at various times city health officer, member of the water board and on the city planning commission; died November 14, aged 63.

Willis C. Trowbridge, Goldendale, Wash.; Union Medical College of Kansas City, Mo., 1900; died November aged 71.

Phoebe May Bogart Van Voast ♂ New York; Johns Hopkins University School of Medicine, Baltimore, 1906; consulting physician at the Morrisania Hospital; died January 1 aged 65, of coronary thrombosis.

Leslie A. Weaver, Ironwood, Mich.; Milwaukee Medical College, 1901; died November 20, aged 69, of cerebral thrombosis.

John Michael Wilson, Brunswick, Mo.; National University of Arts and Sciences Medical Department, St. Louis 1914 served during World War I; died in the Woodland Hospital Moberly, November 27, aged 58, of coronary occlusion.

Samuel Clyde Wilson ♂ Oxford, Pa.; Baltimore Medical College, 1908; found dead November 1, aged 63, of cardiac thrombosis.

Leopold Walter Wuesthoff, Richmond, Calif.; Sioux City College of Medicine, Sioux City, 1903; died November 20, aged 71, of bronchopneumonia and coronary heart disease.

LIEUT. (JG) PHILIP WILLIAM CAREY
(MC), U.S.N.R., 1917-1944

CAPT. RUBIN EVANS
M. C., A. U. S., 1916-1944

CAPT. IRVING ROBERT TEITELBAUM
M. C., A. U. S., 1912-1944

Henry M. Stadt, Glendale, Calif.; St. Louis College of Physicians and Surgeons, 1893; died in Los Angeles November 27, aged 74, of cerebral hemorrhage.

Robert Brown Stille ♂ Many, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1930; interned at the Charity Hospital of Louisiana, New Orleans; for many years director of the Sabine State Bank and Trust Company, resigning in April 1944; died December 26, aged 39, of heart disease.

John Magruder Sutton, Lincoln, Kan.; University Medical College of Kansas City, Mo., 1908; died in the Ellsworth Hospital, Ellsworth, November 22, aged 70, of chronic nephritis and uremia.

Murray Tate, Memphis, Tenn.; University of Tennessee Medical Department, Nashville, 1894; served during World War I; died in the Veterans Administration Facility November 27, aged 62, of cerebral hemorrhage and hypertension.

Charles Curtice Taylor ♂ Cooper, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1894; for three years medical examiner for the Selective Service Board; served as city health officer of Cooper, and county health officer of Delta County; died December 1, aged 73, of diabetes mellitus and ascites.

David Armstrong Taylor, San Francisco; Milwaukee Medical College, 1906; assistant clinical professor of obstetrics and gynecology emeritus at the University of California Medical School; died in the Stanford Hospital January 2, aged 74, of coronary occlusion.

Robert Kirk Young, Detroit; Detroit College of Medicine; 1894; veteran of the Spanish-American War and World War I; died November 25, aged 73, of coronary thrombosis.

KILLED IN ACTION

Philip William Carey, Brookline, Mass.; Harvard Medical School, Boston, 1943; served an internship at the Hartford Hospital, Hartford, Conn.; commissioned a lieutenant (jg) in the medical corps, U. S. Naval Reserve, on April 13, 1943; ordered to St. Albans, N. Y., and later to Camp Lejeune, North Carolina; attached to the first marine division, medical corps, first tank battalion; died in the Pacific area Sept. 16, 1944, aged 27, of a gunshot wound of the chest.

Rubin Evans.—The photograph of Dr. Evans was obtained after publication of his obituary in *The Journal*, January 13, page 117.

Irving Robert Teitelbaum, New York; Universität Basel Medizinische Fakultät, Switzerland, 1937; member of the American Medical Association; interned and later clinical assistant in medicine at the Hospital for Joint Diseases; commissioned a first lieutenant in the medical corps, Army of the United States, on April 11, 1942, later promoted to captain; killed in action in the European area Aug. 8, 1944, aged 32.

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated DDN] and foods, FNJ. The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consignee, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment.]

Bi-Sal Tablets—Oxford Products, Inc., Cleveland Shipped April 7, 1942 Composition in each tablet $\frac{1}{2}$ grain of phenolphthalein, and unnamed amounts of extracts of plant drugs, including nuxvomica and a laxative as well as an extract of bile Misbranded in that the description "Panogestic Enzymes with Bile Salts Compound" was misleading since the product was essentially a laxative and its physiologic activity was due principally to phenolphthalein which is neither an enzyme nor a bile constituent, but a coal tar derivative Also misbranded because of a statement falsely representing that the nostrum would be an effective treatment of gallbladder and bile duct infection Further misbranded because labeling failed to give adequate directions for use or to warn that a laxative should be taken only occasionally when needed—[DDN J, FDC 837, December 1943]

Eez all Germicide for the Skin—Adolph F. Frick, San Francisco Shipped April 3, 1941 Composition small amounts of a phenolic compound and free ammonia with alcohol and water Adulterated because strength differed from what it purported to possess, misbranded in that it was not a germicide or a pain reliever as represented by its name, that it consisted of two or more ingredients, though the label did not give the common or usual name of each and that the label did not bear adequate directions for use—[DDN J, FDC 854 May 1944]

Hanford's Balsam of Myrrh—G C Hanford Mfg Company, Syracuse, N Y Shipped April 11 and May 19, 1942 Composition essentially alcohol water, myrrh, benzoin and chlorothymol Misbranded because labels falsely represented it to be efficacious in treating sprained ankle, frostbite athlete's foot minor skin irritations cuts and bruises, among other things—[DDN J, FDC 834, December 1943]

Hyde Brand Vitamins A, B₁, D, G Capsules—McCambridge and McCambridge Company, Washington, D C Shipped April 18, 1942 Composition not more than 750 U S P units of vitamin D, and only inconsequential amounts of vitamin G per capsule, whereas label claimed that product contained 1,000 units of vitamin D per capsule and represented it as an important source of vitamin G Hence adulterated and misbranded—[DDN J, FDC 877 May 1944] Also misbranded under provisions of the law applicable to foods as reported in F V J 4700

Indian Antiseptic Hair and Scalp Stimulator—Adolph F. Frick, San Francisco Shipped April 3, 1941 Composition essentially small proportions of a phenolic compound and free ammonia alcohol and water Misbranded because name and symbols on label falsely represented that product was of Indian origin and also would be effective in stimulating hair and scalp, treating dandruff, falling hair, eczema and like conditions Also misbranded because not accurately labeled as to quantity of contents, and further, because label did not bear common or usual name of each active ingredient—[DDN J, FDC 854 May 1944]

McDades Prescription—Allan & Co, Inc St Louis, and John G Ayars Shipped between Sept 18 and Oct 1 1941 Composition essentially extracts of plant drugs including a laxative and a bitter drug, glycerin, alcohol and water Misbranded because label claims "Vegetable Alternative—An Aid in the relief of pain and discomfort arising from certain Rheumatism and Catarrhal affections" were false and misleading Also misbranded because label did not give adequate directions for use, particularly as to duration of administering it—[DDN J, FDC 855 May 1944]

Menestrex—Rex Laboratory, Nashville, Tenn Shipped Dec 22 1941 Composition in each capsule 3.43 grains of quinine sulfate and 0.35 grain of potassium permanganate Misbranded because of false label representation that it was an effective treatment for painful scanty or functionally delayed menstruation, and was a scientific preparation—[DDN J, FDC 855, December 1943]

More Pep—Allan & Co, Inc, St. Louis and John G Ayars Shipped between Sept 18 and Oct 1, 1941 Composition essentially extracts of plant drugs including nuxvomica and a laxative drug a small proportion of an arsenic compound, with water, alcohol and sugars Misbranded because name was misleading in representing that the drug would give the user "more pep" Further misbranded because falsely represented as being a sexual stimulant and because label failed to warn that not more than the recommended dosage should be taken (since the mixture contained strychnine and arsenic compound) that frequent continued or prolonged use of the drug might result in serious injury, and that use by elderly persons might be especially dangerous—[DDN J, FDC 855 May 1944]

Q-T—Allied Pharmacal Company, Cleveland Shipped May 22 and July 4, 1942 Labeled in part "Q-T For Adults Only, Contains Gold and Sodium Chloride and Ammonium Chloride . . . This preparation was formerly called Quits" Composition 0.16 grain of gold and sodium chloride and 6.3 grains of ammonium chloride per fluid ounce—[DDN J, FDC 859 May 1944]

Ru-Ma-Dol—Allan & Co, Inc, St. Louis and John G Ayars Shipped between Sept 18 and Oct 1 1941 Composition essentially sodium salicylate and extracts of plant drugs, including an alkaloidal one, glycerin, water and alcohol Misbranded because falsely represented in labeling to be effective in the cure, mitigation treatment or prevention of rheumatism neuralgia, neuritis and swelling and in the relief of symptoms of these conditions—[DDN J, FDC 853, May 1944]

Stevens Concentrated Mineral Water—E A Stevens Dawson Springs, Ky Shipped March 2, 1942 Composition essentially water, magnesium and calcium sulfates, and small amounts of sodium sulfate, sodium chloride, calcium carbonate and potassium chloride Misbranded because, though product was a laxative, label failed to give adequate directions for use, and instead provided for continuous administration whereas a laxative should not be used thus, also misbranded because labeling failed to warn that a laxative should not be taken when symptoms of appendicitis are present, or that frequent or continued use of such a product might result in dependence on a laxative Further misbranded because label statements suggested that product would be efficacious in treating liver, kidney, stomach and blood disorders dropsical trouble rheumatism, malaria, and many other ailments—[DDN J, FDC 814 December 1943]

Texas Crystals—Loyce Distributing Company, Fairmont, W Va Shipped April 8 and May 1, 1942 Composition hydrated sodium sulfate with traces of other inorganic salts Misbranded because, though it was a laxative, its label failed to warn that it should not be taken in cases of nausea, vomiting, abdominal pain or other symptoms of appendicitis, and that frequent or continued use might result in dependence on laxatives Also misbranded because label represented that preparation contained substantial amounts of sodium sulfate, calcium carbonate, sodium chloride, magnesium carbonate, potassium chloride and sodium carbonate, whereas none of these was present in a substantial amount except the sodium sulfate—[DDN J, FDC 812, December 1943]

White Cross All Purpose First Aid Kit—American White Cross Laboratories Inc New Rochelle, N Y Shipped March 16, 1942 Composition gauze and adhesive strips which were not sterile but contaminated with viable aerobic and anaerobic or facultative anaerobic micro organisms Adulterated because below standard of purity and quality represented, misbranded because not sterile and because outside container did not accurately declare quantity of contents—[DDN J, FDC 876, May 1944]

STERILATOR LABORATORIES BARRED

The Post Office Department Rules on Contraceptive Devices

Most of the cases in which the Post Office Department debarred medical devices or treatments from the mails are based on charges of perpetrating a fraud on the public. There are, however, other reasons for denying to individuals or concerns the use of the mails. One is the transmission by this means of devices or medicines for contraceptive use.

Such was the charge against the Sterilator Laboratories, which operated from a number of addresses, including Detroit and Dearborn, Mich, Yonkers, N Y, and Chicago, with a Harold G Johnson as promoter. This company sold through the mails outfits consisting of a vaginal syringe and a jar of jelly-like material. So-called diaphragms for use as a means of covering the cervix uteri were furnished as a separate item.

Investigation showed that Johnson, when renting a postoffice box in Yonkers, described himself as "Dr.," and that later, though retaining that box, he directed the Yonkers postmaster to forward his mail to Dearborn, Mich. Still later he gave the same order regarding mail addressed to him at Chicago.

The label of the jar of jelly-like substance that he sent out with the vaginal syringe stated that the mixture contained tragacanth, karaya, glycerin, boric, citric, tartaric, lactic and acetic acids, potassium alum, "antimol" (whatever that was) and oil of rose compound.

In July 1944 the Post Office Department, after due investigation, called on the concern to show cause at a hearing in Washington why mail addressed to it at its various locations should not be returned to the senders or directed to the Dead Letter Office at Washington, as Johnson's business had been found to be a scheme for delivering through the mails instruments and substances intended for preventing conception.

Johnson neither filed an answer to the charges nor appeared at the hearing of the case. On that occasion the Post Office

Department presented details of the contraceptive treatment and the correspondence regarding it that the Sterilator Laboratories and its promoter sent through the mails to an inquirer. Expert medical testimony introduced by the government at the hearing showed that the outfit and diaphragm which Johnson sent out were not only well adapted for the prevention of conception but could scarcely have any other purpose. It was further brought out that the circular matter mailed by Johnson declared that the articles he sold were "For Physicians Exclusively." On the contrary, the Post Office Department produced evidence that in the actual conduct of the enterprise Johnson's articles were habitually furnished to lay persons through the mails for the purposes mentioned. Accordingly, the Post Office, on Oct. 3, 1944, issued an order debarring the Sterilator Laboratories and H. G. Johnson (under his various designations) from further use of the mails.

Correspondence

METATHYROID-ALLOXAN DIABETES

To the Editor:—De Finis and Houssay (Tiroides y diabetes en el perro, *Rev. Soc. argent. de biol.* 19:94 [June] 1943) found that: 1. The administration of 0.5 Gm. of thyroid powder per kilogram of body weight to normal dogs does not produce diabetes. 2. The same treatment may produce diabetes in dogs with the pancreas reduced to one fifth or less in size by previous operation but with normal glycemia up to the thyroid administration. 3. The thyroid induced diabetes may last not more than the thyroid treatment (thyroid type) or be a permanent one (metathyroid type). 4. Treatment with thyroid may also produce diabetes in dogs with a pancreas otherwise injured by previous treatment with extracts of the anterior hypophysis. According to the Buenos Aires letter in your issue of Dec. 11, 1944 these facts have been insisted on in a recent lecture by Dr. Houssay, who stated that "prolonged administration of thyroid does not cause diabetes in normal dogs, whereas it does cause this disease in dogs with normal glycemia and a pancreas experimentally reduced to 2.5 or 2.3 Gm." and that "the disease may be of the thyroid type, which lasts only during administration of thyroid, or of the metathyroid type, which persists even after discontinuation of the thyroid treatment."

As previously reported (Carrasco-Formiguera, R.: *J. Lab. & Clin. Med.* 29:510 [May] 1944), one of a personal series of dogs injected with diabetogenic doses of alloxan, with a previous normal dextrose metabolism, following the intravenous injection of 100 mg. of alloxan per kilogram of body weight, developed mild diabetes. A biopsy taken on the same day as a diabetic dextrose tolerance test failed to show any pathologic changes in the islets of Langerhans or in any other pancreatic structures. The attack of diabetes was transient. Further observation and experiment on the same animal have shown that the restoration of a normal dextrose metabolism, after a short diabetic period, seemed to be definitive, as shown by several normal dextrose tolerance tests and absence of glycosuria for eleven months. Eleven months after all evidence of diabetes had disappeared, thyroid administration was started and was carried on for more than three months at doses progressively increased from 12.5 up to 75 mg. per kilogram of body weight. Shortly after beginning and several times during the administration of thyroid, dextrose appeared in the urine in an irregular way and in amounts ranging from slight traces up to 0.9 per cent. During the last weeks of thyroid administration and for about ten days after its discontinuance Benedict positive tests were more frequent. A few days later fasting blood sugar was 195 mg. per hundred cubic centimeters. About twenty days after no thyroid had been given, fasting blood sugar was 240 mg. per hundred cubic centimeters and a dextrose tolerance

test gave distinctly diabetic figures. For the last two weeks, up to the moment this communication is being written, nearly one month after the discontinuation of thyroid administration, sugar excretion has ranged between 2.5 and 3 Gm. per kilogram in twenty-four hours.

While I am preparing a more detailed report of this experiment, waiting for more time to elapse before definitely accepting the thyroid induced diabetes as a permanent one and experimenting on similar lines with a wider number of animals, I have thought that this early and rather informal report might be of some interest to the readers of THE JOURNAL, mainly on account of two points: First, in agreement with Houssay's findings, thyroid administration, which does not produce diabetes in the normal dog, has induced this disease in a dog which had a normal dextrose metabolism and a pancreas that had been previously injured in some way (in this particular case by alloxan) to a degree that also was not enough by itself to cause permanent diabetes. Second, it is possible for the pancreas to be injured in such a way and to such a degree (in this particular case by alloxan) that the damage suffered, without being accompanied by any noticeable anatomic change, may in a way be the equivalent of the surgical reduction of pancreatic tissue down to about one fifth or even less of the normal size of the organ.

R. CARRASCO-FORMIGUERA, M.D., Puebla, Pue., Mexico.
Professor of Pathologic Physiology, Laboratory
of Physiology, University of Puebla.

IMMEDIATE CHOLANGIOGRAPHY

To the Editor:—The diagnosis of intraductal lesions in the common duct during operation has been a difficult problem. During the past six years I have found a relatively easy method of accurate diagnosis and, since the method has been substantiated by examinations in 168 consecutive operations performed up to May 1943 as reported to the Surgical Section of the California Medical Association meeting on May 3, 1943, I feel that it should be presented for further consideration. An aqueous solution of iodine (hippuran) in quantities from 8 to 15 cc. is injected through a 24 or 26 gage needle inserted obliquely through the wall of the common duct. An aqueous solution is miscible with bile; therefore it is not necessary to withdraw an equal amount of bile before injection. The injection is made after the common duct has been exposed. A cassette is placed under the patient before the patient is draped for operation. Immediately after the injection has been made an x-ray picture is taken (usually on a 14 by 17 film) at a focal distance of approximately 18 inches; a sterile towel is placed over the focal site and marked with a dot of merthiolate solution. During the period that the x-ray film is being developed the gallbladder is removed and by the time this has been accomplished the technician has returned with the developed film. Therein may be seen obstructive lesions (gallstones, polyps, carcinoma, parasites) or, if the duct is normal, the iodine solution enters the duodenum readily and there is little evidence of obstruction or dilatation of the choledochus. If dyskinesia exists and temporary obstruction occurs it is usually characteristic on the x-ray film but if a subsequent film is taken fifteen or twenty minutes later the sphincter of Oddi has relaxed so that the iodine solution readily enters the intestine.

The success of this method diagnostically and the ease of administering the opaque solution without opening the common duct warrant its widespread use by the general surgeon. Herein lies its great value.

Obstructions of the common duct have been overlooked in approximately 8 per cent or more of all patients being operated on for gallbladder disease during the past twenty years. This

method of immediate cholangiography resulted in only 1 instance of erroneous diagnosis in the 168 cases reported up to May 3, 1943 and the 108 cases performed since then. Its diagnostic value is thereby established, in my opinion.

STANLEY H. MENTZER, M.D., San Francisco.

DIAGNOSIS OF HERNIATION OF LUMBAR INTERVERTEBRAL DISKS

To the Editor:—In the paper on "Diagnosis of Herniation of Lumbar Intervertebral Disks by Neurologic Signs" by Dr. J. Jay Keegan, published in the Dec. 2, 1944 issue of *THE JOURNAL*, reference is made to a manipulative procedure the origin of which could not be found, according to the author. May I call to your attention that this manipulative procedure was described in detail by Dr. Bror S. Troedsson in an article entitled "Lumbosacral Derangement and Its Manipulative Treatment," published in the *Archives of Physical Therapy* (18:10 [Jan.] 1937). Dr. Troedsson also demonstrated his procedure before the annual meeting of the American Congress of Physical Therapy on Sept. 8, 1936, when his paper was read. It seems to me that Dr. Troedsson should receive credit for the manipulative procedure so well described and illustrated in the first part of Dr. Keegan's article.

MEDICOLEGAL ABSTRACTS

Compensation of Physicians: Knowledge of Physician of Third Party's Promise to Pay as Affecting Patient's Liability.—While a customer in a so-called ten-cent store Mrs. Iverson slipped and fell. The store manager directed her to go to the plaintiff physician, who at the expense of the store would render the necessary care. Mrs. Iverson then proceeded with her husband to the plaintiff's office. Prior to their appearance, however, the physician had been advised by some one connected with the store of the accident and that Mrs. Iverson was on her way to his office. Examination by the physician indicated that the patient had sustained a fracture of a bone in the knee and that the injury would require "rather careful and prolonged treatment." When this fact was determined the physician remarked to the patient "that it was fortunate that she fell in the store and not outside because had she fallen outside the store the cost to her of having the injury treated would have been \$100." The physician then proceeded to institute the required course of treatment. At no time during the treatment, except on the very last visit of the patient to his office, did he indicate that he expected compensation from the patient or her husband. At the patient's last visit, however, he suggested that the patient and her husband "give him \$50 because the insurance company would pay him no more than \$15," which the Iversons refused to do. Subsequently the physician sued husband and wife to recover the reasonable value of the professional services he had rendered. From an adverse judgment the plaintiff appealed to the Supreme Court of South Dakota.

The physician contended that on the treatment of a patient by a physician in the absence of an express contract between the physician and the patient to pay for such treatment there arises an implied contract that the patient will pay the physician the reasonable value of the services performed, even though those services are rendered at the request of the third party. With that general statement of the law, said the Supreme Court, there can be no serious dispute; but the question here presented is somewhat different, namely, if there is an agreement between the patient and a third person that the third person will pay for services rendered the patient by the physician and that the patient will not be obligated to the physician, and the physician has knowledge of this agreement and treats the patient at the

request of the third party without any express agreement with the patient relating to his fee, does there arise an implied contract obligating the patient to pay the physician the reasonable value of the treatment? SDC 10.0601 defines an implied contract as one "the existence and terms of which are manifested by conduct." We think it clear, continued the Supreme Court, that under this definition, absent any other facts, there arises an implied contract that the patient will pay the physician the reasonable value of services performed, though such services are performed at the request of a third party. But in this case we are confronted with conduct which in our opinion refutes the existence of an agreement by the defendants to pay for the services performed. Clearly the testimony of the patient establishes an agreement on behalf of the store to assume full responsibility for payment of the physician. The physician's statement to the patient that it was fortunate she fell in the store and not outside because had she fallen outside the cost to her of having the injury treated would have been \$100 supports a belief that the physician knew of the existence of the agreement on behalf of the store to assume full responsibility for his fee, and such belief finds further support in the fact that plaintiff was advised of the accident by the store before the patient consulted the physician and performed the services at the request of the store. When plaintiff proceeded to treat the patient knowing of the agreement between her and the store and at the store's request, such conduct, rather than implying an understanding between physician and patient that the patient will pay the reasonable value of the services performed, implies, in the court's opinion, an agreement by the physician to perform the services according to the conditions and terms under which he is consulted and asked to perform the service. The rule is stated in *Garrey v. Stadler*, 67 Wis. 512, 30 N. W. 787, 789, 58 Am. Rep. 877, as follows:

As the law in such case implies a promise to pay what the service is reasonably worth on the part of the person for whom such service is performed, such implied promise must be overcome by evidence showing that the person performing the service knew that there was a different arrangement for the payment of such service, to which he expressly or impliedly assented.

We believe, continued the court, the evidence of record fairly establishes that plaintiff knew of the arrangement between the patient and the store for the payment of his services, and when he performed the services at the request of the store, without advising or suggesting to the Iversons that he would hold them responsible, he thereby impliedly assented to the arrangement of which he was advised.

The judgment which in effect denied the physician recovery against the patient and her husband was affirmed—*Ophcim v. Iverson*, 16 N. W. (2d) 440 (S. D., 1944).

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Part I. Oral and Written. New Orleans, Sept. 28-29, New York, Oct. 5-6, Chicago, Oct. 12-13 and San Francisco, Oct. 19-20. Final date for filing application is August 1. Sec., Dr. G. A. Caldwell, 3503 Pruitania St., New Orleans 15.

AMERICAN BOARD OF OTOLARYNGOLOGY: New York, June 5-8. Final date for filing application is March 1. Chicago, Oct. 3-6. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: Chicago, May. Final date for filing application is Feb. 28. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington 6, D. C.

AMERICAN BOARD OF RADIOLOGY: Oral. New York, June 3. Final date for filing application is May 1. Sec., Dr. B. R. Kirklin, 102 110 Second Ave. S.W., Rochester, Minn.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Rupture of Mitral Chordae Tendineae.—In the last 2,400 necropsies at the Peter Bent Brigham Hospital, according to Bailey and Hickam, there were eleven instances of rupture of the mitral chordae tendineae. Four were associated with bacterial endocarditis involving this valve. The other 7 patients presented no evidence of bacterial endocarditis and no history of severe trauma to the chest. In each of these cases disease of the valve and its chordae tendineae appeared to antedate the rupture. It is difficult to state in most instances what was the nature of the disease, but in some it was rheumatic fever. There was no difference in frequency of rupture of the chordae tendineae to either of the cusps. In 3 cases the ruptured chordae tendineae were attached to the anterior cusp, in 3 to the posterior cusp, and in 1 case one chorda tendinea of each cusp was ruptured. It has been suggested that accidental cutting of chordae tendineae in opening the heart at necropsy has been confused with antemortem rupture by the pathologist. Especial care was taken in these cases to avoid this error. In several instances the free ends of the chordae tendineae were seen in the valve orifice before the ventricles were opened. Furthermore, the bulbous enlargements of the ends of the ruptured chordae tendineae and the character of the portions on the papillary muscles leave no doubt as to the antemortem nature of the process. The point of rupture lay close to the papillary muscle. The stumps consisted of hyalinized and partially degenerated connective tissue with a covering of endothelium. Scarring extended into the subjacent myocardium. The corresponding papillary muscles underwent atrophy if all their chordae were broken but showed hypertrophy if a number were left attached. Rupture of the chordae must have allowed a high degree of mitral regurgitation. All hearts were dilated

and hypertrophied. The histories did not indicate that external violence or vigorous exertion was an etiologic factor in rupture. The symptoms after rupture of the mitral chordae tendineae are those of congestive heart failure, which may be insidious or abrupt in its onset and progressive or remittent in its course. Months or years may elapse between rupture and congestive failure. Rupture of the chordae is suggested by the sudden appearance of a loud, precordial systolic murmur, maximal at the apex and left sternal border, where it is usually accompanied by a thrill. An apical diastolic murmur may also be present. Auricular fibrillation sometimes occurs. Roentgenograms show cardiac enlargement, and fluoroscopy may demonstrate systolic pulsation of the left atrium. The differential diagnosis includes bacterial endocarditis, rupture of a valve cusp, rupture of a papillary muscle and perforation of an infarcted interventricular septum.

Effect of "Nitrite" Drugs on Blood Pressure.—Weaver and his associates gave glyceryl trinitrate, sodium nitrite, erythrol tetranitrate, mannitol hexanitrate and a placebo to normal and hypertensive subjects and made blood pressure measurements at brief intervals until the effect of the drug was over. Each of the 38 subjects received one or more of the substances and most received all four nitrite drugs. The patients were led to believe that the blood pressure measurements were a part of their routine management. Fifty-one per cent of the subjects who were given the nitrite drugs had a fall of systolic pressure, and 23 per cent had a lowering of diastolic pressure. The systolic fall was almost always greater than the diastolic. None had a fall in blood pressure after the administration of a placebo. The amount of the fall in blood pressure in hypertensive patient varied greatly, but the averages were as follows: glyceryl trinitrate 16/4 mm. of mercury; sodium nitrite 21/1 mm., erythrol tetranitrate 14/5 mm. and mannitol hexanitrate 12/4 mm. In normal subjects the average fall in blood pressure was as much as 10 mm. less than the corresponding figure for the hypertensive. The period between the administration of the drug and the beginning of the fall in blood pressure was variable. For glyceryl trinitrate this interval averaged 2 minutes, for sodium nitrite 7 minutes, for erythrol tetranitrate 35 minutes and for mannitol hexanitrate 55 minutes after the drug was given. The average duration of blood pressure lowering was as follows: glyceryl trinitrate 20 minutes, sodium nitrite 62 minutes, erythrol tetranitrate and mannitol hexanitrate about the same, 256 and 252 minutes respectively. With the last two drugs there was wide variation in the duration.

Infectious Lymphocytosis.—Finucane and Philips describe an epidemic of 21 cases of infectious lymphocytosis which occurred in a children's sanatorium. The children ranged in age from 1½ to 5½ years. The leukocyte counts ranged from 22,500 to 120,000, with a relative lymphocytosis of 62 to 97 per cent. In the majority of the cases the total counts were over 40,000, while in 3 they were over 100,000; in all except 4 instances the percentage of lymphocytes was 85 or over, and in these 4 it was 62 plus. In none of the cases was there any symptom at the onset, the condition being discovered in every instance by routine blood counts. The average probable duration of the leukocytosis was approximately 4½ weeks, the longest 7 weeks and the shortest 2½ weeks. In the majority of cases eosinophilia appeared as the total count began to drop. In a few this occurred during the highest count and persisted for seven months. The authors believe that the cause of this condition is an infectious agent, but efforts to demonstrate a bacterial or virus cause in these cases were fruitless.

Hereditary Periodic Paralysis.—According to Oliver and his associates, periodic family paralysis is characterized by the periodic development of acute flaccid paralysis, which usually begins in the extremities and progresses toward the trunk. The

patient loses the power to move his limbs, but he can usually breathe, eat and speak freely, and the functions of his internal organs appear not to be disturbed. The deep reflexes of the affected extremities are absent at the height of the attack. After a period of time, usually a few hours, but in some instances two or three days, the patient recovers from the attack spontaneously. Another attack may occur within twelve to twenty-four hours or after a longer interval. During the attacks the levels of serum potassium and inorganic phosphorus tend to be low, while during periods of freedom they are normal. The attacks are often preceded by excessive exercise, fatigue or ingestion of an excess of carbohydrates during the previous day. Attacks can usually be induced in persons who have the potentiality for them by the administration of large amounts of carbohydrate or by the use of certain agents, such as insulin and epinephrine, which are known to lower the level of serum potassium. The familial occurrence of periodic paralysis has been recognized, according to Talbott, since the report of Shakhnowitsch in 1882. The authors present the pedigree of a family of Scandinavian ancestry, 16 members of which have had periodic attacks of paralysis. The trait behaves in this family as a mendelian dominant with full penetrance but with varied manifestations. The manifestations, as shown by the age of onset and the frequency, duration and severity of the attacks and the duration of the disease are as varied as those observed when nonrelated affected persons are compared.

Hemolytic Disease of Fetus.—According to Wiener and his associates, the usual method of demonstrating Rh sensitivity is to test the patient's serum for anti-Rh agglutinins, as was first done by Wiener and Peters. It was soon discovered that there is a high percentage of persons with Rh negative blood who are highly sensitive to the Rh factor whose plasma does not contain demonstrable anti-Rh agglutinins. These puzzling cases have been explained, at least in part, by the discovery that in addition to Rh antibodies that produce hemagglutination there are Rh antibodies able to combine specifically with Rh positive cells without producing a visible reaction. If Rh positive blood is mixed with serum containing antibodies of the latter type, the blood loses its capacity to be agglutinated by anti-Rh agglutinating serums, presumably because all the combining sites on the erythrocytes have been occupied. Because of this property of blocking the action of anti-Rh agglutinins, the new type of antibody has been named the blocking antibody. The blocking antibody has served to explain the hitherto puzzling lack of correlation between the titer of anti-Rh agglutinins and the severity of hemolytic disease in the infant. A biologic test of detecting Rh sensitivity was described by Wiener in 1942. This test has proved particularly useful for the prevention of hemolytic reactions to intragroup transfusion in the absence of the facilities or the time for carrying out tests for the Rh factor. The biologic test consists of intravenous injection of 50 cc. of blood to which the patient may be sensitive and comparison with the naked eye of the color of the patient's original citrated plasma with that of a comparable specimen taken one to one and one-half hours after the injection. If sensitivity is present the second sample of plasma will be distinctly darker, and not infrequently the patient will have a chill fifty to sixty minutes after the test is started, followed by a rise in temperature. In case of doubt an additional 50 cc. of blood may be injected and a third specimen of the patient's plasma obtained for comparison after one more hour. If the reaction to this test is negative, any quantity of blood from the same donor can be given without untoward effect. The authors describe some experiences with the application of the biologic test for the detection of sensitivity to the Rh factor caused by pregnancy. In a woman who had previously had repeated miscarriages, a negative biologic reaction proved that these were not caused by Rh sensitivity, even though her blood was Rh negative and her husband's was Rh positive. On the other hand, in a case involving a husband with Rh positive blood and a wife with Rh negative blood, who had had two stillbirths of obscure cause, a positive biologic test proved that isoimmunization was responsible, even though in vitro tests for anti-Rh agglutinins in the woman's serum had previously given negative results. Two cases of hemolytic disease of the newborn are

described in which transfusions of Rh negative blood were given. In 1 case the therapy was dramatically life saving, while in the second, in which the disease was apparently milder, the infant died of cholemia and kernicterus.

Congenital Absence of Lung.—Ferguson and Neuhauser report 5 cases of agenesis of the lung encountered at the Children's Hospital in Boston during the past six years. In all of these the condition was diagnosed during life by bronchoscopy followed by iodized oil roentgenograms of the tracheobronchial tree. These 5 cases of agenesis of the lung illustrate the fact that this deformity is not incompatible with a normal existence, since 4 of the 5 patients are living normal lives and are not handicapped by their defect. All 5 cases showed additional congenital anomalies. In the first case the left hand was absent. In the second there were a patent ductus arteriosus, accessory spleen with hypoplasia and hypoplasia of the kidney and liver. In the third case there was a congenital malformation of the external ear. In the fourth there were congenital anomalies of the vertebrae and ribs noted by the roentgenograms. In the fifth there was a harelip and a complete cleft palate. The cases in the literature also have shown frequent associations of other congenital anomalies. The authors feel that an inherent defect in the germ plasma is probably responsible for this as well as the other associated congenital anomalies. The symptoms are so inconstant or lacking that x-ray studies plus bronchoscopy with injection of the tracheobronchial tree with iodized oil are the recommended methods for diagnosis. The prognosis should always be guarded, although the condition is compatible with longevity. In 3 of the cases reported in the literature the age was well over 50 years. Of

the 5 patients whose histories are presented 4 are living normal lives and the oldest is 8 years old. The authors stress that in cases of persistent emphysema or atelectasis, of supposed unresolved pneumonia or of recurrent pneumonia in the same lobe, congenital anomalies of the tracheobronchial tree must be considered.

Rib Fractures in Atypical Pneumonia.—In the course of an epidemic of so-called virus or atypical pneumonia during the winter of 1942-1943 several instances of fractured ribs, according to Harvey, were noted. A review of the literature on atypical pneumonia did not reveal previous descriptions of the occurrence of rib fractures. A consecutive series of 500 cases of atypical pneumonia occurring in a station hospital was reviewed. In 19 there was evidence of recent rib fractures. In 1 a history of trauma was elicited, but in all others trauma was excluded as a possible etiologic factor in the production of the fractures. A review of the original roentgenogram would usually disclose a definite fracture line. The appearance of the fracture line and the subsequent development of callus left no doubt as to the fracture having occurred recently. In 10 of the 18 cases the fractures were not recognized until a routine review of the entire series was made in a definite search for them. In half of the patients the fractures were multiple. All fractures occurred in the anterior axillary or axillary line. It has been postulated that this is due to the opposing forces of the serratus anterior and externus obliquus abdominis muscles. The occurrence of rib fractures was not related to the severity of the pneumonia. Associated with atypical pneumonias is a severe, dry, irritating cough which is probably a factor in the production of the fractures. Excessive chest pain occurring in cases of atypical pneumonia should direct the search of the roentgenologist toward this complication in order that the fractures may not be overlooked. This complication may explain many supposed cases of pleurisy in atypical pneumonia.

Powdered Blood Cells for Wound Healing.—Seldon and his associates of the Mayo Clinic used powdered blood cells in the treatment of wounds. One bottle of powdered blood cells was set aside for each patient to avoid cross contamination from

the wounds of 1 patient to another. Dressings of powdered blood cells were applied every one to three days, the frequency depending on the type of wound. If the wound was moist as there was considerable serum or seropurulent drainage, daily dressings were applied. Cells were applied each time the dressings were changed. Certain wounds had a urea-like odor after application of powdered blood cells. Occasionally during the first five to seven days the application of the powdered blood cells produced a burning and painful sensation. In the first five to seven days there is no appreciable growth of tissue. The time of first growth and of the disappearance of the pain is almost simultaneous. Therefore it is felt that the growth of new tissue may cover the little nerve fibril endings and thus prevent direct stimulation of the nerves. The base and wall of the ulcers or wounds do not change during the first five days of treatment with these cells. If the ulcers are old they are grayish red and many times appear more or less devitalized they continue to look this way for the first few days of treatment. The first few applications of powdered blood cells tend to draw from the underlying tissues a quantity of serum. The cells take up this serum and become moist to a point that a thin gelatinous liquid is present. Sometimes this liquid has been suspected of being purulent drainage, although many cultures have proved it otherwise. After five to seven days of treatment there is usually a slow and steady ingrowth of both granulation tissue and epithelium. In some cases the granulation tissue has been so exuberant that it had to be burned down with silver nitrate to allow the epithelium to cover it. The healing of wounds or ulcers has usually required from three to five weeks. Although dried blood cells do not always produce healing, they are so satisfactory in a large number of cases that they have therapeutic value.

Spontaneous Retinal Reattachment.—According to Knapp the course of serous retinal detachment is sometimes curiously modified when the detachment of the retina remains stationary and there is reattachment, which gives rise to a characteristic ophthalmoscopic picture. This condition is observed in a small percentage of cases and only when the detachment occupies the lower half of the eyeground. The detachment is shallow, and its upper boundary is bound down by chorioretinal changes, which constitute the most striking sign. The retina in the course of time becomes reattached except for small areas in the extreme periphery, where there are one or more holes or an area of dialysis. The reattached, flat retina is generally changed to a paler, yellow gray; there are characteristic branching white subretinal lines and areas where the choroidal markings are more distinct and irregular retinal pigmentation is present. The author describes 18 cases in which reattachment of the retina had taken place. The field defect cannot be restored by late operation in cases of retinal reattachment; it remains stationary and permanent. Central vision depends on involvement of the macula. The only object of an operation in a case of late detachment is to preserve the macular area if it is not firmly shut off, and the feasibility of this operation depends on the extent and the age of the macular change. Notwithstanding

the prospect of self limitation of a retinal detachment which is limited to the lower half of the fundus, an early operation should be performed to avoid involvement of the macula and to preserve the visual field.

Rabies.—The efficiency of antirabies vaccine for dogs is debatable. Most authorities believe that from 65 to 80 per cent of dogs will be protected by its use. Martin states that in Arizona the incidence of rabies in animals is unusually high. Every dog which bites any one should be isolated for a period of not less than ten to fourteen days. If he is still healthy and active at the end of fourteen days the likelihood of that animal having been infectious at the time of attack is very remote. If the dog dies within that time, the head of the animal should be sent to a competent laboratory for the examination of the brain substance to determine whether or not Negri bodies are present in the nerve cells, particularly in Ammon's horn. The animal should not be shot unless it is impossible to catch it. Treatment of the bitten person with antirabies vaccine is not without danger, but the danger of complications becomes less as the vaccine becomes more refined. All wounds caused by the animal should be thoroughly cleansed with soap and water and then cauterized. If the wound is in the shoulder, neck or forearm, treatment with vaccine should be started at once. If the area of injury is on the extremities or elsewhere, it is considered safe to wait until the dog has been observed. If the animal cannot be found and a definite break in the skin has been made, treatment is advisable. If the patient has had only casual contact with the dog, which later proves to be rabid, but with no direct injury, it is advisable to give treatment to the contact if less than 12 years of age.

Cerebral Form of Malaria.—Fitz-Hugh and his associates report statistical data on 140 cases of cerebral malaria encountered during the six months that ended in October 1943. These cases constitute 2.3 per cent of the total series of 6,059 cases of malaria. Among the 1,764 American patients with malaria there occurred only 2 deaths, whereas among the 4,295 patients of an allied nation 38 deaths occurred. Both deaths in the American group occurred in patients with *Plasmodium falciparum* infections, and 32 of the 38 deaths in the other group occurred also in patients with this infection. Cerebral malaria is chiefly a result of *P. falciparum* infection. *Falciparum* (estivoautumnal, malignant tertian) malaria is truly a protean disease. Within the category of cerebral malaria there are many and varying manifestations. The cerebral phenomena resulting from plugging of the capillaries by plasmodia, pigment laden leukocytes and erythrocytes vary from minimal to the most violent. Cortical irritation, subcortical, brain stem, basal ganglions, frontal lobe, parietal lobe, cerebellar and hypophyseal

syndromes may be observed, with or without the phenomena of generalized cerebral edema. Photophobia and vertigo were frequent complaints. A moderate number of patients developed sudden severe cerebral symptoms one to three days after admission with, and routine treatment of, what appeared to be ordinary malaria. The neurologic phenomena are variable and may change with remarkable rapidity. Some patients are alternately rigid and flaccid. Not uncommonly there is a moderately stiff neck without a Kernig or Babinski sign and with absent knee jerks. Contrariwise there may be transiently positive Kernig and Babinski signs, exaggerated knee jerks and abortive clonus, with or without stiff neck. The management of cerebral malaria calls for a "high index of suspicion" and prompt coordinated action on the part of ward officers, nurses and ward masters. These patients constitute true medical emergencies. Day and night vigilance and prompt measures to meet the shifting requirements are essential. Some of the early, merely somnolent patients can be cajoled and "stimulated" into sufficient cooperation to make oral quinine therapy and oral fluid administration possible. The nasal catheter route of administration of quinine, atabrine, fluids, salt and sugar is useful in many cases. The greater was the authors' experience with intravenous administration of quinine dihydrochloride, the less became their fear of this procedure. Transfusion of blood or plasma brought a number of patients out of coma, caused the disappearance of pulmonary edema and seemed to make the difference between life and death. A considerable number of patients have awakened from coma following spinal fluid drainage. An initial tap is always justifiable in comatose patients or those with stiff neck. The intravenous administration of epinephrine proved of value to certain comatose patients. The authors have learned to rely on total doses of 3 to 4 Gm. of quinine each twenty-four hours in cerebral or severe *falciparum* malaria. This should be maintained for two or three days and then reduced to about 2 Gm. daily until the patient is out of danger of relapse. A few cerebral cases in group B have been treated and cured solely with atabrine. For the maniacal or convulsive patient intravenous sodium amylal is most useful.

Typhoid in Alberta from Cheddar Cheese.—Menzies reports that in the 1944 outbreak in Alberta 83 cases of typhoid were reported, with 7 deaths. Questioning revealed that all the sick persons had eaten fresh, green cheddar cheese. The suspected cheese was withdrawn from the market and an investigation was started among the people supplying milk to the cheese factory in which the cheese had been prepared. It was learned that milk was being shipped by 96 different families, 223 members of which gave histories of handling milk in one way or another. Of these 223 persons 19 gave histories of previously having had typhoid, 51 gave histories of contact with typhoid and 82 gave histories of remote contact. The remaining 81, many of whom were adolescents born in the district, gave histories which more or less ruled out their being the agent responsible for the outbreak. Three samples of stool (on different days) and one urine sample were obtained from each member of the two groups first mentioned. Single samples of stool and urine were obtained from the third group. No testing was done on the remaining 81 persons. As a result of this procedure 1 carrier was detected among the first group giving a history of having previously had typhoid. This woman, aged 38, had had the disease in Russia in 1919. All 3 of her stool samples were positive. All other samples obtained from the other 141 persons proved negative. The typhoid organism was not isolated from the cheese. The cheese tested was 48 and 63 days old. In view of the work of Campbell and Gibbard on the survival of *Eberthella typhosa* in cheese it was hoped that the actual organism would be isolated, but such was not the case. Why the typhoid organism should survive for as long as 336 days in artificially inoculated cheese and be absent in ordinary infected cheese 63 days old is an open question.

Statistical records indicate that the period of incubation of the disease was from fourteen to twenty-one days. There was evidence to show that the typhoid organism was still alive for approximately one month after the date of manufacture but nothing to indicate that any cases were contracted by eating infected cheese of greater age. Phage typing afforded an additional means of assuring that the organism isolated from the carrier, viz. type E, was the same type as that found in 6 of the cases chosen at random. The problem was such in the opinion of the Provincial Board of Health that legislation was necessary to prevent further outbreaks. As a result of this decision, regulations respecting the sale of cheese in the province of Alberta were to go into effect on Dec. 1, 1944. These regulations require that cheese either be pasteurized or be stored for at least three months following manufacture before being allowed to appear on the open market.

Comparison of Insulins.—Of 350 well controlled diabetic patients treated by MacBryde and Reiss in four years only 186 could be regulated with protamine zinc insulin alone, while 164 required in addition a separate morning injection of regular insulin. The authors show that if the majority of moderate and severe cases of diabetes are to be controlled with one daily injection, some different modification of insulin will prove necessary. The authors investigated several insulin modifications. They give particular attention to a standard modified protamine zinc insulin having the same pH as market protamine zinc insulin (7.2) but containing only half the added protamine and zinc. Approximately 75 per cent of this insulin is in precipitated, slowly absorbed form, while 25 per cent is in solution and is rapidly absorbed. In 16 comparative case studies, modified protamine zinc insulin gave better control in 13 patients than globin zinc insulin. In no case did globin zinc insulin establish better regulation than modified protamine zinc insulin. Globin zinc insulin failed to prevent after-breakfast hyperglycemia in 12 of the 16 cases and caused afternoon hypoglycemia in 9 of the 16. Fasting blood sugars were higher in 13 of the 16 cases when globin zinc insulin was used. Even when special diets were employed, allowing a smaller breakfast

and a larger lunch, the same defects in control were observed with globin zinc insulin. In ten direct comparative studies with an extemporaneous mixture made with 2 parts of crystalline insulin and 1 part of protamine zinc insulin, modified protamine zinc insulin gave better control in every one of the 10 cases. Irregular results were obtained with the mixture, with failure to duplicate twenty-four hour curves. The rise in blood sugar after breakfast was poorly controlled with the mixture and there was a tendency to hypoglycemia at midafternoon or at night. In a total of 110 case studies conducted over a one year period, good regulation was established in 98 patients; a single injection of modified protamine zinc insulin daily. Severe as well as mild cases were well controlled. The authors think that the use of multiple forms of insulin should be discouraged. They think that two forms of insulin should be sufficient. (a) modified protamine zinc insulin such as that used in these studies, which might well be substituted for standard protamine zinc insulin since it will control a much larger percentage of patients with uncomplicated diabetes, and (b) regular (or crystalline) insulin for use in diabetic emergencies and whenever supplementary insulin is required.

Chemical Studies in Hypertension.—Holden describes the determination of nonfermentable reducing substance and non-urea nitrogen in protein free blood filtrates from hypertensive subjects. The patients are classified into two groups, one with normal, the other with elevated blood nonprotein nitrogen level in an effort to demonstrate corresponding variations in the fractions under consideration. Appreciable amounts of nonfermentable reducing substance were noted in 30 of 38 zinc filtrates from patients with hypertensive disease and in 4 of 21 control filtrate. A similar difference was found in tungstic acid filtrates. Among the hypertensive subjects the nonfermentable reducing substance in zinc filtrates exhibited some tendency to vary with non-urea nitrogen. No direct relation to blood pressure or urea clearance could be demonstrated.

Testosterone Compounds in Thyrotoxicosis.—Thyrotoxicosis is characterized by an increase in the urinary excretion of nitrogen and creatine and by a decrease in body weight. Testosterone propionate has the opposite effect of these three variables. Kinsell and his co-workers investigated the metabolic effect of testosterone propionate and methyl testosterone on 3 patients with thyrotoxicosis. Testosterone propionate induced a positive nitrogen balance in these patients and caused a weight gain; these effects were obtained in patients whose diet was constant and even in individuals whose caloric intake was less than their caloric expenditure. Methyl testosterone had a similar initial effect on the nitrogen balance, but its effect was not sustained. The difference between methyl testosterone and testosterone propionate may possibly be attributed to its different calorogenic effect of the former or, more probably, to its different effect on creatine metabolism. Testosterone propionate decreased the hypercreatinuria which characterizes thyrotoxicosis; methyl testosterone increased it. It is suggested that methyl testosterone may increase creatine formation at the expense of protein anabolism. In the 1 patient with thyrotoxicosis in whom calcium studies were carried out, there was with testosterone propionate therapy a striking reduction in

the hypercalciuria characteristic of thyrotoxicosis. The effect of testosterone propionate in reducing the serum potassium level was confirmed in 1 patient. Testosterone propionate improved the clinical status of thyrotoxic patients, methyl testosterone, on the contrary, aggravated their toxicity. The latter drug is probably contraindicated in this disease. Testosterone propionate may prove to be a useful therapeutic adjunct in preparing for operation thyrotoxic patients who have sustained severe weight loss, with emaciation and muscle wasting. A daily dosage of 12.5 mg. is probably adequate. Thus should be given in addition to whatever drug is used to reduce the metabolic rate—iodine or thiouracil.

Renal Excretion of Sulfamerazine.—Earle made simultaneous measurement of the renal plasma clearance of the drug and the rate of glomerular filtration under different experimental conditions. Measurements also were made on the extent to which sulfamerazine is bound to the nondiffusible constituents of plasma, presumably plasma albumin, since it is only the unbound drug in the plasma water that is presented to the glomeruli for filtration. The ratio of the unbound drug clearance to the concurrent rate of glomerular filtration (excretion ratio) yields information on the extent to which the filtered material is reabsorbed or excreted by the renal tubules. The addition of a methyl group to the pyrimidine ring of sulfadiazine to form sulfamerazine results in a compound that has a very low overall renal excretion rate. This is the result of extensive reabsorption by the renal tubules and binding on plasma proteins. The N^4 -acetyl derivative of sulfamerazine (which is presumably its conjugated form) is secreted rather than reabsorbed by the renal tubules. The low overall excretion rate of sulfamerazine has two distinct therapeutic advantages: (1) relatively infrequent and small doses are required to maintain any given plasma concentration, and (2) the urine concentration of the drug at any given plasma level is less than that of other sulfonamides in current use. Such a circumstance should minimize the renal hazard of sulfonamide therapy, but additional factors such as solubility, urine flow and pH may be expected to operate in this respect. An increase in the excretion rate of sulfamerazine accompanies augmented electrolyte elimination. This occurs when the electrolyte excretion is increased by a variety of means. The renal excretion of sulfamerazine does not appear to be simply related to the rate of urine formation. Indirect evidence suggests that sulfamerazine is reabsorbed by an active transport system in the renal tubules, but this has not been directly demonstrated.

False Positive Serologic Tests for Syphilis.—A positive test in a candidate for induction into the armed forces of the United States may be the basis for rejection. The findings of the Committee on Medical Research of the Office of Scientific Research and Development are discussed by Davis. The incidence of transient positive tests following acute infections depends largely on the frequency of testing during the acute and convalescent stages. Although postinfectious or postvaccinal positive reactions occasionally last as long as three months, most become negative within a few days or weeks. Since it is customary to perform serologic tests on hospital patients only on admission, at which time acute infections have not fully developed their antibodies, it is likely that the ability of many common infections to lead to false positive serologic tests is grossly underestimated. False positive serologic tests are common (more than 10 per cent of cases) in leprosy, malaria in the acute stages, infectious mononucleosis, vaccination against smallpox, rat bite fever due to *Spirillum minus*, relapsing fever, lupus erythematosus and possibly certain types of atypical pneumonia. There is no reliable evidence that the serologic tests are significantly affected by pregnancy, menstruation, scarlet fever, jaundice (other than infectious), subacute bacterial endocarditis, tuberculosis or hypoproteinemia. Inadequate data are available on measles, mumps, infectious hepatitis, lymphopathia venereum, chancroid and many other diseases. Transient false positive reactions may occur in apparently normal persons without recent illness. Even persistently positive reactions may occur in nonsyphilitic patients. Since a large proportion of seropositive patients have no syphilitic lesions at necropsy, it is entirely possible that many seropositive persons without a history or signs of the disease have been mistakenly diagnosed and treated for latent syphilis. In large serologic dragnets the number of innocent victims may be large, and the psychologic, social and legal consequences to the individual may be serious. A positive serologic test is not an emergency. The most important procedure, in the absence of pregnancy, is a probationary period of at least three months before starting treatment. While many false positive tests will be revealed as transient during this period, there is no verification test available today to help in the diagnosis of those which remain positive.

proved malarial patients. Two thirds of the patients with falciparum infection had an enlarged liver. This was a somewhat higher incidence than among the vivax cases or among those in whose thick films plasmodia were found, but the species of plasmodium could not be identified. The enlargement of the liver, like that of the spleen, seemed to follow the course of the disease. It was not palpable at the onset of the disease but enlarged during the first few days of fever and tended to remain so during the duration of symptoms. It grew smaller as the fever subsided under treatment. The consistency of the enlarged liver varied considerably. Liver tenderness was present on palpation in 8 of the 59 patients. The liver involvement is attended by impaired hepatic function, as shown by increased van den Bergh readings of blood bilirubin, but rarely reaching the stage of obvious jaundice and by sulfobromophthalein retention. Impairment of function, like enlargement of that organ, varies with the activity of the disease. The liver condition may give rise to anorexia, occasionally to nausea and vomiting, and perhaps to other vague symptoms that might be called "cachectic." The enlarged liver is at times tender to palpation and in rare instances is painful, suggesting the possibility of liver abscess. The presence of liver involvement is not an evidence of chronicity. The nature of the liver change is uncertain; at most it may be a swelling of the parenchymal cells and attendant compression of the sinusoids, plus the finding of malarial pigment in the Kupffer cells. The authors recommend the use of a high carbohydrate, high protein, low fat diet in malaria to spare the liver from further damage.

Relapsing Malaria.—Metcalf and Ungar analyze observations on a series of 250 cases of malaria, all except 2 of which were in men who had been evacuated to this country following the initial engagement in the Solomon Islands. On return to the continental limits all patients were admitted to a naval hospital, where malarial smears were made. In the absence of clinical malaria and with negative smears many patients after a relatively short time were granted thirty to forty days' sick leave and permitted to go to their homes. Many became acutely ill while on leave and were forced to seek treatment at or near their homes. These relapses did not seem to respect any particular climate or altitude. The cases described here are chronic relapses, benign tertian in type. A low parasitemia was capable of producing a severe rigor. The figure has been as low as 9 parasites per cubic millimeter of blood. This is in contrast to the findings in natives inhabiting malarious areas, who frequently are shown to harbor a tremendous number of parasites with no clinical manifestations. Even in the American forces at this comparatively early date many cases with parasitemias but no clinical disease have been reported. These cases are added evidence that we do not have as yet any drug or combination of drugs adequate for coping with the malaria problem. It is fortunate in view of the quinine shortage that atabrine is available. This drug has a meritorious record in malignant tertian malaria. Its efficacy in the benign tertian type is considerably less. Atabrine failure is not due to insufficient dosage, since large doses were given. Quinine in large doses has been much more effective in these cases. The ideal drug for eradicating plasmodia, particularly the latent form recently termed the cryptozoite, may well be found to be a colloidal plasmodicide having a special affinity for the reticuloendothelial system. Such a compound has been evolved by combining high molecular pectin solutions with various soluble plasmodicides. Toxicity studies are promising, but as yet no opportunity for using the substance in experimental malaria has been afforded.

Air Embolism in Immersion Blast.—Gouze and Hayter carried out experiments to determine whether air enters the circulation in blast injury to the lungs and, if it does, what part it plays in the sudden death observed in severe blast injury. One guinea pig and 9 rabbits were used. Postmortem observations on animals subjected to fatal immersion blast revealed frequent air embolism of varying degree. The authors believe that early death in blast is caused by (a) air embolism, (b) reduced respiratory function and (c) insufficient flow of blood from the left ventricle. Data from necropsies on human victims dying soon after blast are needed. It is suggested that victims of blast injury be compressed in an air chamber.

Filariasis.—Johnson analyzes 189 cases of filariasis occurring in Marines, the majority of whom had been examined by the Filariasis Board in the South Pacific and returned to the Marine Corps Base in San Diego. The mean incubation period, the time elapsing between arrival in an infested area and the development of symptoms was nine and a half months. The symptoms observed were fatigue, headache, drowsiness, blurring of vision, dysuria, a chilly sensation at times and backache. There is a wide variation in symptoms. Two conditions consistently observed are swelling of the affected part and tenderness of the involved area, especially during recrudescence. The lymphangitis was usually of a descending type rather than the classic ascending type of lymphatic infection. Lymphadenitis was not always centrifugal, for axillary nodes were sometimes found when epitrochlears were not palpable. In quiescent cases the forearm is often found to be slightly indurated in the upper third. Involved glands in the wrist and in the neck were not uncommon. The legs showed less involvement. Patients with lesions elsewhere complained of pain in the popliteal region and in the thigh on the medial aspect without palpable glandular enlargement. The scrotal lesions presented considerable variation. The testis and epididymis were as a rule but slightly enlarged and somewhat abnormal on palpation. The increased fluid in the tunica could be seen readily during exacerbations. Large inguinal glands were commonly found. During intervals the most consistent indication of having had filariasis was a thickening of the spermatic cord. Even in cases of pronounced swelling there was a moderate degree of pain. Exercise produces an increase in pain and swelling. The effect of climatic variables is uncertain. Damp weather and genuinely hot weather apparently tend to promote relapses. The patients showed a great improvement after being within the United States more than one hundred and seven days. The proper psychologic approach to patients having filariasis greatly reduced their requests for extended hospitalization.

Penicillin in Primary Atypical Pneumonia.—In the first of Short's series of cases of atypical pneumonia the administration of penicillin led to a sudden and sharp temperature decline, disappearance of symptoms and rapid convalescence. Eight additional cases have been treated, all of which responded more or less promptly to the drug. A control series was not observed, but results with penicillin seemed to be much superior to those with the expectant, symptomatic treatment formerly used. The average number of days from the institution of penicillin therapy until the temperature became normal and remained so was 3.5. This is decidedly less than the usual expectancy with supportive treatment.

Human Milk Intoxication Due to B₁ Avitaminosis.—Fehily discusses the high infant mortality in China. Some deaths occur suddenly in apparently healthy, well fed and well cared for babies. Sometimes the mothers observe that their infants suddenly become cyanotic and dyspneic and die, apparently of suffocation. In such cases women believe that suffocation is due to "wind." They believe that this "wind" is transmitted to the infants through their own milk, which is considered to be "no good." Actually the belief that their milk is not good has been scientifically proved. In 1888 Hirota in Tokyo was the first to observe a complex of symptoms in infants fed by beriberic women, and he called this complex infantile beriberi. It is now known that in B₁ avitaminosis, owing to a reduction of certain coenzymes, the intermediary products of incomplete carbohydrate oxidation accumulate in the tissues, organs and body fluids, including human milk. These intermediary metabolites are believed to consist of lactic acid, acetoacetic acid, glycuronic acid, glyceraldehyde, acetaldehyde, dihydroxyacetone, methylglyoxal and others. One of these substances—methylglyoxal—has been shown to be actively toxic and, as it is never found in the milk of healthy women, it has been suggested that this product is the toxic factor in the milk of B₁ avitaminotic women. Various authors have stated that other intermediary products, if in excess, are toxic. The amount of pyruvic acid and sodium pyruvate in the milk of B₁ avitaminotic women seems beyond the infantile tolerance. Human milk intoxication is not restricted to China but occurs whenever the staple foods of women are vitamin B₁ deficient carbohydrates. An apparently healthy mother with latent B₁ avitaminosis may produce milk containing intermediary metabolites just above the infant's tolerance, which would lead to predisposition to infantile complaints such as respiratory infections or persistent intestinal catarrhs. Accumulation of intermediary metabolites in the milk of lactating women may be encountered in conditions other than B₁ avitaminosis, such as acidosis, ketosis, anoxemia, toxemia and uremia.

Psychometric Method of Determining Intellectual Loss Following Head Injury.—According to Reynell, from 15 to 20 per cent of moderate or severe head injuries are followed by persisting intellectual impairment, causing loss of efficiency often increased by psychoneurotic symptoms arising from such incapacity. Deterioration of powers of sustained attention, of recent memory and of emotional control are charac-

teristic after severe head injury, but ignorance of the patient's previous capacity and personality makes estimation difficult. The method described by the author has been used by him in a military hospital for head injuries during the past eight months. It requires from twenty to thirty minutes and uses a differential test score based on tests described in Wechsler's "Measurement of Adult Intelligence." Wechsler claimed that cases of organic cerebral injury or disease showed lower scores on arithmetical reasoning, digit retention and "relational thinking" than in vocabulary, general information and comprehension, and that such differences could be used as an index of intellectual impairment. Wechsler used a battery of ten tests of which the author has selected six. Three of these, called A series, have all been found to hold up well in cerebral injury and disease; the remaining three—the B series—all tend to fail away in such conditions. The reliability of such a method as a clinical instrument depends to some extent on the experience of the user. About 10 per cent of cases with clinical evidence of intellectual loss may pass through the sieve, but in doubtful cases other tests—especially Kohs's block design tests and digit symbol, which also hold up badly in association with intellectual deterioration, should be used as supplementary tests. The author performed the test in 520 consecutive cases of head injury referred for psychiatric examination. Of these 120 cases gave a positive result on the A and B series, i. e. a difference of 10 or more between the intelligence quotients calculated on the two series of tests. Ninety-five of these were cases of moderate or severe head injury. Three hundred cases gave a significant difference between the two test scores; 90 of these were cases of moderate or severe head injury. One hundred cases were found to be "dull and backward," i. e. with intelligence quotient 60 to 85. The results in these cases were not considered to be of great significance. The best index of a man's lowered efficiency is incapacity when returned to his usual work. In the majority, this acid test of efficiency was not available. It was therefore necessary to judge the validity of a positive finding by fitness or unfitness for further military service. Eighty per cent of 100 positive cases were found by medical boards, which were uninfluenced by the result of the A and B tests, to be unfit for further service; 80 per cent of subjects who were negative by the same differential test—although all were cases of moderate or severe head injury—were returned to duty.

*Notes on Use of Duck and Turkey Eggs for Large Scale Preparation of Epidemic Typhus Vaccine. A. P. Berkowitz.—p. 109.

Duck and Turkey Eggs for Large Scale Preparation of Typhus Vaccine.—Berkowitz used duck eggs for the preparation of typhus vaccine. He found that the average yield of vaccine per duck egg harvested on the seventh or eighth day after inoculation is 100 to 200 cc. This is approximately five times the average yield of vaccine from hen's eggs. Stained smear preparations in a high percentage of yolk sacs show almost a confluent sheet of rickettsias, quite beyond anything seen even in the most heavily infected hen's egg. A further advantage of the use of duck eggs consists in the fact that, since the yield per yolk sac is so high, the residual proteins are correspondingly diluted, thus rendering subsequent processing easier. Preliminary protection tests in guinea pigs indicate that duck egg vaccine is at least equal in protective value to that made from hen's eggs. Comparative tests were also carried out with turkey eggs. The growth of epidemic typhus rickettsias in the yolk sac of turkey eggs is at least as prolific as that in duck eggs, the yield of vaccine being as great. The best conditions for the primary incubation of duck eggs is 102 F. in a completely humid atmosphere.

Book Notices

Modern Clinical Syphilology: Diagnosis, Treatment, Case Study. By John H. Stokes, M.D., Professor of Dermatology and Syphilology, School of Medicine and Graduate School of Medicine, University of Pennsylvania, Philadelphia, Herman Beerman, M.D., Sc.D., Assistant Professor of Dermatology and Syphilology, School of Medicine and Graduate School of Medicine, University of Pennsylvania, and Norman R. Ingraham Jr., M.D., Assistant Professor of Dermatology and Syphilology, School of Medicine, University of Pennsylvania. Third edition. Cloth. Price, \$10. Pp. 1,332, with 911 illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

In comparison with the second edition, the third may be described as "more meat on a smaller skeleton." Condensation has been achieved by increased use of fine print and deletion of less important material, for some of which the reader is referred to previous editions. The excellent illustrations and text figures have been reduced in number from 973 to 911. Two chapters remain of the same size and six, including a new one on penicillin therapy, have added 99 pages, while sixteen chapters have been shortened a total of 119 pages. The chapter on the examination of the patient, illustrating methods popularized by Stokes and now well known, have been deleted, although at least one illustration has been used elsewhere. The material in the entire text has been brought up to date, and a chapter on the preliminary results of treatment of syphilis by the wonder drug, penicillin appears for the first time in a textbook on the disease.

The disconcerting problem of biologically false positive serologic reactions is discussed fully, and some sixty diseases and states are listed as causative, with reported percentage of positive reactions. "Verification" tests are not recommended as wholeheartedly as their value would seem to indicate. Adequate space is devoted to intensive systems for the public health treatment of early syphilis.

Increased interest in prevention of prenatal syphilis is reflected in enlargement by 19 pages of the chapter on familial and prenatal syphilis. The all important chapter on public health and military medicine is 40 pages longer than the corresponding one in the second edition. Herein are included public health and military aspects of syphilis, including prostitution, prophylaxis, epidemiology, a blueprint of venereal disease control and an organization chart of a city department of public health venereal disease program.

As stated in the preface, the text telescopes three books into one: "for the student, as illustrated in the summaries and the principles; for the practitioner, as illustrated in details and cases; and for the expert, as shown by the discussions and references to the literature." Pertinent references are given parenthetically throughout the text.

Treatment systems recommended are standard American systems for use in various phases of the disease. However, it would seem that the general practitioner might easily select an unsatisfactory method of treatment. For instance, use of a system approaching the Eagle-Hogan method for early syphilis, which has been recommended, among others, for the treatment of neurosyphilis, might result in even a higher percentage of toxic reactions than has been experienced in the treatment of early syphilis. The value of rest and rest periods is appropriately emphasized, but the latter are not obvious in the systems of treatment for late latent and late neurosyphilis. The value of bismuth compounds is pointed out, but all systems of therapy seem to be predominantly arsenical. Directions for terminating treatment seem to be unnecessarily vague.

The work of Stokes, Beerman and Ingraham remains the best single volume textbook for students, practitioners and specialists ever written on diagnosis, treatment and case study of syphilis. It more than ever deserves the recommendation afforded the first edition by a leading European professor of dermatology who presented it to his students as a "ganz wundrous Buch."

Report on the Incidence of Rickets in War-Time. By The British Paediatric Association. Reports on Public Health and Medical Subjects No. 92, Ministry of Health. Paper. Price, 25 cents; 9d. Pp. 36. New York: British Information Services; London: His Majesty's Stationery Office, 1944.

The purpose of the investigation was to determine whether there had been any change in the incidence of rickets during wartime. A total of 5,283 children between the ages of 3 months and 18 months were examined. They were selected from

twenty-three centers in the British Isles. The authors point out the great difficulty in the clinical diagnosis of mild rickets and also emphasize the fact that the radiologic diagnosis may often be in doubt. Of the 5,283 children, 106 were found to have radiologic evidence of rickets. In the children from 3 to 6 months of age the incidence was 2.5 per cent, between 6 months and a year 4 per cent, and practically none beyond this age. The clinical diagnosis of rickets showed great variability in different centers, being nil in some and as high as 61 per cent in others. The correlation between the clinical and the radiologic diagnosis of rickets was extremely poor. As a result of their studies the investigators conclude that there has been no demonstrable increase in the incidence of rickets in Great Britain during the war.

Fractures and Fracture Treatment in Practice. By Kutt Colsen, M.D., Tutor to the Department of Surgery, Registrar to the Surgical Firm of the University of the Witwatersrand, Johannesburg. Second edition. Cloth. Price, 12s. 6d. Pp. 154, with 163 illustrations. Johannesburg: Witwatersrand University Press, 1944.

This book is based on the author's course in surgery at the University of the Witwatersrand in Johannesburg, South Africa. His demonstrations have been amplified by a number of simple diagrams and a succinct manuscript which should help the medical student grasp the important features involved in the treatment of fractures. The aim of the book is to present a concise review in response to requests from students preparing for examinations and general practitioners desiring a review of the subject. Attention has been paid more especially to the clinical side of fractures and their treatment. He has accomplished his purpose, especially in view of the more frequent occurrence of bone injuries brought about by the increasing number of war, industrial and traffic accidents, which has made the subject of fractures more and more important for students and practitioners. This small book was not intended to serve as a substitute for the many excellent large textbooks on fractures. The diagrams are simple and instructive. The author acknowledges his indebtedness to Böhler's "The Treatment of Fractures" and R. Watson Jones's "Fractures and Other Bone and Joint Injuries." The book can be recommended highly to the practicing physician and surgeon.

Sulphonamides in the Treatment of Meningococcal Meningitis. Report to the Scientific Advisory Committee, Department of Health for Scotland. Paper. Price, 10 cents; 4d. Pp. 20, with 2 illustrations. New York: British Information Services; London: His Majesty's Stationery Office, 1944.

In this pamphlet is presented a study of 2,223 cases of meningococcal meningitis observed in Scotland from 1936 to 1941. The figure stated represents about 40 per cent of all reported cases. Statistics show the effects of different methods of treatment, and comparisons are made in fatality rates before and since the introduction of chemotherapy. The authors believe that antitoxin or serum in combination with the sulfonamides does not promote therapeutic efficiency. However, this view is based apparently on the theory that, with the combined method, antitoxin or serum would be administered intrathecally. No definite preference is expressed for any one of the three sulfonamides used. Most of the patients received sulfapyridine, and the fatality rate for these was 17.17 per cent. For smaller groups the sulfanilamide rate was 9.37 and for sulfathiazole 14.6. The rate with serum or antitoxin alone was 51.76, but presumably these patients were treated intrathecally—not by the intravenous method of Hoyne. In discussing the complications occurring during treatment with the different drugs, it was found that sulfanilamide secures a less permanent and rapid effect than either sulfapyridine or sulfathiazole, and that pneumonia was a more frequent complication. Patients treated with the combined method, serum and drugs, required a much longer stay in the hospital than those to whom the drugs alone were administered. It is stated that the sulfonamide drugs have caused a reduction in the fatality rate to 16.7 per cent. Attention is directed to the fact that mortality is greatest under 2 and above the age of 35. Tables and graphs clearly illustrate the analysis of the cases studied. The report reveals what may be anticipated when treating cerebrospinal fever with sulfonamides.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

EFFECT ON SYPHILIS OF PENICILLIN TREATMENT FOR GONORRHEA

To the Editor:—Penicillin is being used for the treatment of acute gonococcal urethritis. In the follow-up, serologic tests for syphilis are taken to determine if there might not have been concomitant infection with this organism. Is it known whether or not the use of penicillin before the appearance of the primary chancre would have any effect on the development of this lesion? Would it have any effect on the serologic reaction in doses of 100,000 to 200,000 units?

P. T. Green, M.D., Winnipeg, Man.

ANSWER.—There have been a number of reports of a delayed incubation period for primary syphilis after the treatment of the patient for gonorrhea with 100,000 to 200,000 units of penicillin. Such subcurative treatment for syphilis given for gonorrhea may either lengthen the incubation period of simultaneously acquired primary syphilis or suppress the primary lesion of the disease altogether, the existence of syphilis being subsequently recognized only by means of routinely repeated serologic tests of the blood. Because of this suppressive action of penicillin, it becomes the more essential to perform routine serologic tests for syphilis in all gonorrhea patients treated with penicillin, if possible monthly for three months following treatment, or as a minimum three months after the completion of penicillin treatment. There is no information as to the effect of 100,000 to 200,000 units of penicillin given in one day on the blood test of a patient with an already existing positive serologic reaction.

KELOIDS FOLLOWING REMOVAL OF PIGMENTED MOLES

To the Editor:—Six months ago I began removing several small pigmented unelevated moles from the face and neck of a girl aged 12 by injecting several drops of procaine hydrochloride under each lesion and then touching lightly with an electric needle. Good results with almost no scar were obtained on the first four. The last two I did about three months ago; at the site of each of the latter there is now a keloid, one 3 mm. in diameter at the tip of the chin and the other 5 mm. in diameter midway between the angle of the left ala nasi and the lip. The elevation of each is about 1 mm. Is there any reasonable expectation that these will subside spontaneously? If not, what is the correct treatment? How soon must treatment be attempted?

M.D., South Dakota.

ANSWER.—These lesions probably will not subside spontaneously. Radiotherapy is the correct treatment. It is essential in giving such treatment that the normal skin to the edge of the lesion be shielded with lead foil. Radiotherapy in the amount of 225 roentgens, unfiltered, should be given once a month; an erythema should be avoided. It is difficult to set the maximum number of such treatments, but in a case like this probably four treatments would suffice. During the course of treatment the skin should be observed frequently and carefully for evidence of injury.

PULL ON ABDOMINAL MUSCLES AFTER INCISION

To the Editor:—Since there has been a trend toward getting patients out of bed the same day as their operation and making them walk early, we have been wondering how much lateral pull (pounds) is placed on the incision: (a) when the patient is lying quietly in bed; (b) when the patient is standing; (c) when the patient is coughing, sneezing and vomiting. What is the number of pounds pull on a vertical or longitudinal incision as opposed to the transverse? If disruption should occur, a person who opposes early ambulation might say that the disruption would not have occurred had the patient not been standing.

Raymond L. Evans, M.D., Sayre, Pa.

ANSWER.—Sloan (Sloan, G. A.: *A New Upper Abdominal Incision, Surg., Gynec. & Obst.* 45:678 [Nov.] 1927) measured in man the force required to bring the ends of severed transverse fibers together after a longitudinal abdominal incision with the patient lightly anesthetized. The tension was measured with spring scales attached to several forceps. The same procedure was applied to a transverse incision in which the rectus muscles had been cut transversely. He found that the longer the longitudinal incision, the more force was required to bring the ends of the fibers of the divided aponeuroses together. In a 3 inch longitudinal incision immediately after the incision is made and before the oblique muscles have retracted the aponeuroses, about pounds of pull will bring the aponeuroses together during

light anesthesia; while in a 4 inch incision it will require nearly 50 pounds to bring the ends of the aponeuroses together. If the incision is lengthened to 5 inches, it will require about 80 pounds. Sloan deduces that the lateral pull on the suture line following a longitudinal abdominal incision is in proportion to the square of the length of the incision. When complete relaxation is not present, the lateral abdominal tension is about thirty times as great as the vertical; therefore the strain on the suture line of a longitudinal incision is thirty times as great as that on the suture line of the transverse incision. The lateral pull on the incision is greatly increased when the patient is coughing, sneezing or vomiting. Measurements of these increases have not been undertaken thus far. Sloan's is the only attempt to measure the pull of the abdominal muscles following incision.

IMPAIRED HEARING IN VETERAN

To the Editor:—A patient has lost 50 per cent of his hearing following prolonged exposure to gunfire. This occurred over a six months period and has persisted for a year following removal from the locale of the gunfire. The patient is bothered also with persistent tinnitus. Various methods of therapy have been employed without success, including vitamins and histamine. I should like suggestions as to therapy and, more particularly, psychotherapy in the way of reading material that would assist the patient in understanding and in adapting himself to his condition. He is beginning to withdraw somewhat from his friends. Perhaps he are some simple textbooks that might assist him. He is 22 years old, a high school graduate, and of more than average intelligence for his scholastic achievement.

Captain, M. C., A. U. S.

ANSWER.—The tendency for the patient to withdraw from his normal social contacts is unfortunately more or less typical of those with impairment of hearing, and it is essential that assistance be given to prevent any permanent damage to his personality. In many cases, particularly when hearing loss has been sudden, psychiatric treatment has been helpful. The following reading material might be helpful: "Lip Reading, Principles and Practice" by Nitchie, new edition, the Frederick & Stokes Company, New York. "How to Help Your Hearing," by Louise M. Neuschütz, Harper & Brothers, Publishers, New York, 1940. "Your Hearing: How to Preserve and Aid It," by Wendell C. Phillips and Hugh Grant Rowell, Publishers, D. Appleton and Company, New York, 1932. In addition, reprints of articles on subjects relating to hearing problems may be obtained at low cost from the American Society for the Hard of Hearing, 1537 Thirty-Fifth Street N.W., Washington, D. C.

The fitting of the hearing aid and providing lip reading instruction are important means of assisting a patient with impairment of hearing to make an adjustment to his condition. An all inclusive program of diagnosis, treatment and rehabilitation of returned veterans has been adopted in at least three general hospitals. The American Red Cross also assists the deafened veteran in his return to his home community and in the interpretation of his condition to his family. In several areas there are local societies for the hard of hearing.

METAPHEN AND UNDULANT FEVER

To the Editor:—I understand that in some naval hospitals metaphen is being used intravenously in the treatment of undulant fever. I have been unable to find any information on this subject. Could you give me the dosage, technic and administration as well as the dangers of this form of treatment? What are the results of this method?

M.D., Arizona

ANSWER.—Apparently the first published use of metaphen in the treatment of brucellosis was by A. C. Fortney (*Minnesota Med.* 16:335 [May] 1933). He treated 1 patient in the early severe phase of disease, administering 10 cc. of the undiluted 1:1,000 solution intravenously on two occasions, six days apart. The patient became afebrile and asymptomatic six days after the second injection and is known to have remained well, with a high specific agglutinin titer, for at least one month.

No other references with either precise or quantitative information have been found, but there are at least four reviews, written by careful students of this disease, which state that the therapeutic properties of metaphen are not proved, are discouraging or are disappointing; e. g., Angle and Algic (*J. Kansas M. Soc.*, 41:233 [June] 1940), Simpson (*Ohio State M. J.* 36:1053 [Oct.] 1940), Tice's Practice of Medicine, 1940, volume 4, page 106, Barr's Modern Medical Therapy in General Practice, Baltimore, William Wood & Co., 1940, volume 2, page 1324.

Owing to the variability of human brucellosis in severity and duration and to its remarkable features of latency, late relapses and recrudescences, uncontrolled therapeutic studies on small numbers of patients have little value. At present there is no single form of treatment known that gives wholly reliable results in this infection.

THE SURGICAL TREATMENT OF PROLAPSE OF THE UTERUS

RICHARD W. TELINDE, M.D.
BALTIMORE

There is no subject in gynecology which can evoke more discussion among gynecologists than the treatment of uterine prolapse. In several clinics in this country vaginal panhysterectomy is done almost routinely to cure this condition; in others the Watkins interposition operation is the standard treatment, in others the Manchester operation is done and in still others extensive vaginal plastic work is combined with some type of intra-abdominal suspension. In general there has been a trend in the past two decades toward doing the entire procedure by the vaginal route unless intrapelvic disease necessitates laparotomy. It is my opinion that one should not approach the subject with a fixed plan of operation. Each case should be judged and treated as an individual problem. In selecting the best operative procedure in an individual case several factors must be taken into consideration. The most important of these factors are:

- The general physical condition of the patient.
- The desirability of preserving menstruation.
- The desirability of preserving the childbearing function.
- The degree of descensus.
- The condition of the cervix and corpus uteri.
- The presence of, and degree of, cystocele.
- The presence of, and degree of, rectocele or enterocele.

All of these factors will be considered in discussing the various operative procedures discussed in this paper for the cure of prolapse and allied conditions.

As I express my opinion on the various operations and their indications I realize fully that there is room for honest difference of opinion on this subject. There is no doubt that in many cases equally satisfactory results may be obtained by more than one method. If this were not true there would not be such strong adherents of the different types of procedure. It is assumed that each surgeon who strongly defends a particular operation does so believing that that procedure is giving satisfactory results in his hands. There is no doubt that the skill of the individual operator, in a particular operation, is a great factor in his results. But no matter how skillful one may become in a favorite procedure one should never permit one's enthusiasm for it to overcome one's judgment as to its indications.

From the Department of Gynecology, Johns Hopkins University and Hospital.

Read before the Section on Obstetrics and Gynecology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

ANATOMIC CONSIDERATIONS.

In discussing the cure of prolapse of the uterus it is advisable to consider, first, the supporting structures which have failed to hold the uterus in correct position and how best to utilize these supporting structures in restoring the uterus to its normal position or in supporting that portion of the uterus which is permitted to be retained and/or the vagina.

The structures which are concerned in maintaining the uterus in normal position are:

The round ligaments.

The uterosacral ligaments.

The bases of the broad ligaments (cardinal ligaments: ligamentum transversalis colli, Mackenrodt).

The fascia lying between the anterior vaginal wall and the vagina (subvesical fascia or pubovesicocervical fascia).

The fascia lying between the posterior vaginal wall and the rectum.

The floor of the pelvis (the pubococcygeal fibers of the levator ani muscles).

The function of the round ligaments is to draw the uterus forward to its normal anatomic position after it has been displaced backward physiologically by bladder distention or by pregnancy. Once returned to its normal position forward, the intra-abdominal pressure on the posterior surface of the uterus holds it forward. Increased intra-abdominal pressure, such as that caused by straining at hard work or defecation, causes slight temporary descent of the anteposed uterus. If the supports of the uterus are adequate, the uterus promptly returns to its former level. When the uterus is congenitally retroposed, or when the round ligaments fail to bring it forward after physiologic displacement backward, intra-abdominal pressure tends to force the uterus downward into the vagina like a piston in a cylinder. If the other supporting structures are sufficiently firm, the uterus may be maintained at its normal level despite the mechanical disadvantage of retrodisplacement, but a greater strain is put on the other supporting structures than when the uterus is anteverted.

The uterosacral ligaments, which are part of the endopelvic fascia lying subperitoneally, extend from the cervix back to the sacrum; they hold the cervix back and also aid in holding it up. Congenitally long ligaments, or ligaments which have lost their tonus as the result of pregnancy, permit the cervix to be displaced forward and downward; this allows the corpus to be displaced backward until the axis of the uterus and that of the vagina coincide. Intra-abdominal pressure then can work to advantage in forcing the uterus down in the vagina.

comfortable with some type of pessary. It is not within the scope of this paper to discuss the indications for and proper use of the various types of pessaries.

Since the Spalding-Richardson operation for prolapse is not generally known and since I have found it

mucosa clip grasps the urethral meatus and slight traction is made on it anteriorly. If the cystocele is large, the midline of the anterior vaginal wall is grasped with a succession of mucosa clips from the urethral meatus to the cervix so that the mucosa may be put on a stretch. A transverse incision is made through the reflexion of the anterior vaginal mucosa onto the cervix about 1 or 2 cm. from the external os. The point of a Mayo scissors is inserted beneath the mucosa in the midline and the anterior vaginal wall is separated from the bladder in the midline by alternately opening and closing the scissors. The mucosa clips are successively removed as each is reached. As each segment of 3 or 4 cm. is separated, the vaginal mucosa is cut in the midline, ultimately forming the usual inverted T shaped incision, as in the first step of the cystocele operation.

The bladder is then dissected from its attachment to the cervix, first with the scissors, and then a line of cleavage is found which may be followed with the finger until the vesico-uterine pouch of peritoneum is reached (fig. 5).

The edges of the vaginal flaps which have been grasped with mucosa clips are spread out by assistants and the pubovesicocervical fascia is dissected from each flap (fig. 6). In the midline this fascia is quite thin, but laterally it is usually quite sturdy.

The cervix is next amputated. Different technics are permissible for this, but I prefer the technic as shown in figure 7. The posterior lip of the shortened cervix is covered with a flap of mucosa which has been dissected free and then drawn into the canal with a mattress suture. The cervical amputation is much less bloody if the cervical branches of the uterine vessels are first ligated bilaterally.

The vesico-uterine pouch of peritoneum is incised as indicated by the dotted line in figure 6 and the fundus delivered. I have found that traction sutures placed at successively higher levels in the uterine corpus are very useful for this. If the fundus is large and delivery difficult it is usually a drier procedure to make the delivery by traction sutures than by tenaculum. If the fundus is small it may be easily and quickly delivered either by traction sutures or by tenaculum. If the fundus is so large that it is brought forth with difficulty, a wedge shaped piece may be excised as in figure 7.

The uterine end of the round ligament, tube and ovarian ligament are triply clamped *en masse*, cut and doubly ligated with number 2 chromic catgut. This is repeated on the opposite side (fig. 8). A supra-vaginal amputation is done at the desired level. Before

Spalding Richardson operation for uterine prolapse.

such a satisfactory procedure, the technic is here described:

With the patient in the lithotomy position and after the usual vaginal cleansing the anterior lip of the cervix is grasped and the cervix drawn to the outlet. A

making the amputation, the ascending uterine vessels are clamped and ligated below the point of amputation as shown in figure 9. It is well to make this a V shaped cut, as is done in abdominal supravaginal hysterectomy, to facilitate closure. Closure of the stump is

The pubovesicocervical fascia is then brought together in the midline by interrupted sutures of number 0 chromic catgut beginning beneath the urethra, continuing beneath the base of the bladder and finally covering the stump of the uterus (fig. 11).

The anterior lip of the cervix is then covered over with vaginal mucosa, flaps of which have been trimmed down to the proper size for closure (fig. 12). The closure of the vaginal incisions laterally, and of the midline incision, completes the operation (fig. 13).

The pelvic floor and rectocele are then repaired as indicated by the degree of relaxation and size of the rectocele. If an enterocele is present, it likewise is repaired.

In the private service of E. H. Richardson and of R. W. TeLinde and in the public ward service of the Johns Hopkins Hospital the operation has been performed on approximately 100 women. Many of these have been done too recently to be of value in a follow-up study. About a year and a half ago we got back for questioning and examination 33 women who were

operated on from five years to six months before. All 23 private patients in the group had excellent anatomic results and were completely relieved symptomatically. Among 10 public ward patients there were 3 who did not admit complete relief. In 2 of these there was a perfect anatomic result, but in the third there was a moderate cystocele with slight stress incontinence. Among these public ward patients there were, of course, the overworked women with few social advantages, few intellectual resources and multiple complaints. Since the anatomic result was perfect in 2 of these 3 women, I feel that it is scarcely justifiable to attribute their incomplete relief to the operation.

done with interrupted or figure 8 stitches of number 2 chromic catgut as shown in figure 10. The cut ends of the tubes and of the round and ovarian ligaments are sutured to the stump, as indicated in figure 10.

The isthmic portion of the uterus which remains is shown in the diagram in figure 14. It will be noted that it has an ample blood supply. The uterosacral and bases of the broad ligaments are attached to this remaining segment, and these structures are utilized in building up support of the vagina.

The edge of peritoneum formed by entering the vesicouterine peritoneal pouch is then sutured to this

remaining portion of the uterus. It is well to make the suture posterior to the incision line in the uterine musculature so that, in case there is any postoperative hemorrhage, the bleeding will be external and not intraperitoneal.

The Spalding-Richardson operation meets the desired objective of an operation for uterine prolapse when further pregnancies are not desired. The diseased portion of the cervix is removed, thus removing a source of leukorrhea and a potential site of neoplasm.

The corpus uteri is removed and with it the danger of endometrial cancer as well as fibroids. The bases of the broad ligaments and the uterosacral ligaments have not been crushed as in vaginal hysterectomy and are preserved for support of the vagina. Our follow-up study shows that the vagina is well suspended and is of normal depth and caliber.

Fig 14—Spalding-Richardson operation for uterine prolapse: Diagram indicating the portion of the uterus that remains. Note that blood supply is intact.

My chief purpose in describing this operation and its results in detail is to stimulate interest in this relatively new operation. Only by the widespread use of any new operative procedure can its general usefulness be evaluated.

101 West Read Street.

ABSTRACT OF DISCUSSION

DR. GEORGE H. GARDNER, Chicago: Every one agrees that it is desirable to approach the problem of treating uterine prolapse with an open mind: i. e., no single operation is applicable to all cases, and each patient must be individualized. Dr. TeLinde mentions many factors which should be considered in selecting the most appropriate operation, viz. (1) the patient's general physical condition, (2) the advisability of continuing the menstrual phenomenon, (3) the desirability of preserving the childbearing function, (4) the degree of descensus, (5) the condition of the cervix, (6) the condition of the corpus, (7) the degree of cystocele, (8) the degree of rectocele and (9) the presence and/or degree of enterocele. All of us would do well to consider each of these factors systematically before operating on any prolapse. Then we could not routinely employ any one operative procedure on every patient. Dr. TeLinde mentions the various ligamentous and fascial structures responsible for maintaining the uterus in its normal position. However, we doubt if he has emphasized adequately the importance of the cardinal or Mackenrodt's ligaments in the problem of prolapse. He also refers to various stages of prolapse as first degree, second degree and third degree. It is regrettable that he does not define these terms, so that those of us from the hinterland could understand what they denote on the Atlantic seaboard. I question the advisability or referring to the Spalding-Richardson operation for prolapse as a new procedure. To my knowledge vaginal supracervical hysterectomy with extensive plastic repair has been employed in Chicago for many years in the correction of prolapse. One has difficulty in recognizing the advantages of this operation over removal of the uterus in toto. Consequently I wish that Dr. TeLinde had told us more about the postoperative course of these women. I am not pleased with the incidence of complications after vaginal hysterectomies with extensive plastic repairs that I have performed

to correct a uterine prolapse complicated by pronounced cystocele, rectocele and enterocele. Too many of these women have a febrile convalescence, and a considerable percentage have vaginal drainage about a week after operation. I would be tempted to employ the Spalding-Richardson operation more frequently if Dr. TeLinde could give assurance that it is rarely followed by these annoying complications.

DR. ROLAND S. CRON, Milwaukee: Dr. TeLinde presents the problem of the surgical treatment of prolapse of the uterus in a practical, logical and scientific manner. One must agree with his statement that the type of operation performed should fit the needs of the individual case. Certainly no one operative procedure should be utilized as a routine. One hundred consecutive case histories from my private practice dated before 1942 showing various degrees of uterine prolapse with associated pathologic conditions in the pelvis have been reviewed. It was found that vaginal hysterectomy was the operation of choice in 47. Of this group 19 were classified as having a third, 17 a second and 4 a first degree descensus. The average age was 56. The next largest group, comprising 18 patients, 1 of whom had a first, 7 a second and 2 a third degree prolapse complicated by extensive cystocele formation were served by the Watkins transportation operation. The average age was exactly the same. The Manchester Fothergill operation with appropriate plastic additions was used in 10 per cent of the cases. This was the procedure of choice when the lesser degrees of procidentia and cystorectocele formation were found to be present in the patient of more advanced age. A modified type of Simpson suspension of the round and approximation of the sacrouterine ligaments combined with a vaginal plastic procedure was considered to be sufficient for 9 patients, all in the childbearing age and presenting a similar degree of procidentia. Another 10 per cent of the patients, well advanced in years, experienced a cervical amputation with plastic correction of the bladder and posterior vaginal walls. The remaining 6 patients had amputation of the cervix and fundus, plus plecting of the bladder fascia and perineorrhaphy according to the Spalding-Richardson technique. Neither the LeFort colpocleisis nor ventral fixation of the uterus was utilized in this series. Suturing of the fundus to the anterior abdominal wall is most unphysiologic, and frequently the adjacent adnexa become involved in a mass of adhesions. The procedure often fails to correct permanently the prolapse and in itself affords no support to the cystocele. As a matter of fact, polyuria and dysuria often follow. The best end results were uniformly obtained following vaginal hysterectomy. Failures have been frequently observed following the Watkins technique. Excellent results were obtained with the Manchester Fothergill operation. The Spalding-Richardson principle should be an ideal procedure for the lesser degrees of prolapsus. Has the author obtained the same satisfactory results in the patient presenting complete procidentia with huge cystocele formation? Following the correction of a large cystocele, a previously competent urethral sphincter may become incompetent and stress incontinence may appear. A Kelly stitch or Berkow type of urethral elongation, angulation and reconstruction operation will usually correct this annoying symptom.

DR. J. E. CANNADAY, Charleston, W. Va.: I have found that in some cases of uterine prolapse, especially those in which the floor of the pelvis is badly herniated, a definite suspension and fixation of the cervix may possess certain advantages. The procedure that I have carried out occasionally has been about as follows: 1. Preliminary conization of the cervix is done for the purpose of eliminating as far as possible the possibility of the recurrence of cancer. 2. Any indicated vaginal repair is done. 3. After sub-total hysterectomy the cervical stump is drawn upward and total hysterectomy the cervical stump is drawn upward and firmly attached to the periosteum of the tuberculum pubis by the use of a strip of fascia lata or, preferably, a strip of skin from which the epidermal layer has been removed. This strip of cutis is taken from the edge of the abdominal incision. It makes most satisfactory fixation material. In my experience no recurrence of prolapse has been noted. I believe this method gives permanent support.

DR. JOHN M. FALLON, Worcester, Mass.: Of some 600 operations for prolapse done by my father and myself only a few were Richardsons, but I liked the operation. One doctor asked what advantage it had over vaginal hysterectomy. It

leaves the suspensory apparatus attached to the uterus although giving enough exposure to tighten it if needed. That may be an advantage. It may be some disadvantage that carcinophilic cervical tissue remains. The difference between the Richardson, vaginal hysterectomy, interposition or Manchester is small compared to the difference between any one of those and abdominal suspension. Vaginal operations go to the site of the disease, the suspensory apparatus. Abdominal operations suspend a symptom. Results are what one would expect. I summarized some of them in the *New England Journal of Medicine* in 1939. The principle of vaginal approach, although still not universally accepted, was proved long ago. The possible exception to the rule of vaginal operations is the woman who will have more children. Most of us still use the suspension operation, but I prefer the Manchester done without amputation of the cervix. This is another little known operation first proposed, as far as I know, by J. W. A. Hunter of Manchester in the *British Medical Journal*, June 18, 1938. You might be interested in still another excellent operation which seems relatively unknown: a colpocleisis by Labhardt of Basel (*Schweiz. med. Wchnschr.* 64:643 [July 14] 1934). It has replaced the LeFort (more properly Neugebauer) in my regard. A perineorrhaphy continued upward across the introitus to the level of the urethra, this Labhardt avoids the Neugebauer's pull on bladder and urethra and, being more outside the body, is better adapted to the worst possible situations, the old and feeble who are natural candidates for colpocleisis.

DR. CHANNING W. BARRETT, Chicago: Prolapse is a wandering of organs in the abdomen, usually downward. In the man and in four footed animals it is downward, but in man it is toward one wall, the caudal wall, and in the four footed animals it is toward the ventral wall. The stomach, the transverse colon and the gallbladder are prolapsed because they have wandered downward, but eventually they might come through the umbilical opening and become a hernia. We should be foolish to continue the consideration of this as a prolapse and talk about operating on prolapse of the stomach when it was down in the umbilical opening, but that is just what we are doing with these other conditions. They are prolapsed as long as they are downward, and any structure may travel downward, and eventually many of them might come to the pelvis and lie against the pelvic floor, but when they find an opening and go through that opening they are no longer prolapse in the clinical sense. They become something altogether more important. They become hernias, and as hernias they take on new phases of disturbance. Their circulation is disturbed. Their pedicle is disturbed. Their function is disturbed, and so we are dealing with the condition known as hernia. In a herniation shall we leave the uterus in or shall we take the uterus out? That depends on the pathologic condition in the uterus. Nearly all herniations of the uterus can be saved if the age of the patient and the pathologic condition in the uterus demand their being left. Is this herniation severe enough so that the bladder is herniated badly and the rectum is herniated badly and they must be attended to? If so, we must do something to hold the bladder up and to hold the rectum up and either take the uterus out or put it back in position. There are different things to cure the hernia of the uterus. First we must give a good pelvic floor, that is, the caudal wall to the abdomen. Next we must change the vaginal direction so that it goes from the symphysis back to the hollow sacrum, because it is a principle of support to have that wall at an oblique direction. Next we must lessen the vaginal opening so that the vaginal wall will not prolapse through there. The ring for the hernia is in the pelvic floor. The vagina, the uterus and the rectum are a part of the herniated structure.

DR. U. J. SALMON, New York: The Spalding-Richardson operation is a valuable addition to gynecologic surgery. I should like to draw attention to a surgical procedure for the cure of prolapse which is technically simpler and which has been used with consistently good results at the Mount Sinai Hospital of New York during the past twelve years, viz. the parametrial fixation operation. This is a modification of the Donald-Fothergill-Manchester operation, which was introduced by Dr. Robert T. Frank in 1932. In 1937 I reported in the *American Journal of Obstetrics and Gynecology* a series of 254 cases of

prolapse (consisting of 126 cases of first degree, 55 cases of second degree, 35 cases of third degree and 8 cases of prolapse of the cervical stump) which had been treated by the parametrial fixation operation during the preceding five years. There was only 1 case of recurrence of the prolapse in this series. In the intervening seven years the same operation was performed in approximately 200 more cases, with approximately the same satisfactory results. The operation has a number of advantages over other surgical operations for prolapse: 1. The comparative simplicity of technic permits of its standardization and facilitates its being taught to residents. (During the past several years the majority of operations were performed by the residents or junior staff members.) 2. Morbidity and mortality are low. 3. The coital function of the vagina is not compromised. 4. The operation does not preclude the possibility of subsequent pregnancy. 5. If necessary the oviducts can be ligated at the same time by the vagina. It seems to me that the parametrial fixation operation approaches very closely the theoretical desiderata of the ideal operation for prolapse, viz., anatomic as well as physiologic restitutio ad integrum with a minimum of risk to the patient.

DR. R. C. AUSTIN, Dayton, Ohio: My efforts to obviate the shortcomings of the vaginal hysterectomy began a few years ago and I have done 79 of these procedures. The results have been highly satisfactory, far more satisfactory than any type of procedure that I have done, and having been brought up on the vaginal hysterectomy and the interposition operation, I feel that I can make a comparative statement. Some shortcomings or some criticisms of this procedure have been its technical difficulties. It is not too technical. The average time for the operation is about an hour and fifteen minutes. Another criticism has been that the cervix that is left remains the site of a possible neoplasm. Dr. TeLinde did not emphasize that he usually cones out the cervix, as we usually do. I have been highly pleased with the results of this operation.

DR. C. GORDON JOHNSON, New Orleans: The importance of correcting the pelvic floor has not been thoroughly emphasized, and I am quite sure that the majority of instances of recurrence of uterine prolapse that have followed the simple abdominal procedure are due to the fact that the relaxation of the pelvic floor has not been recognized and has not been adequately taken care of. The utilization of shortening of the uterosacral ligaments has not been emphasized. This is of importance in keeping the cervix in its proper place. In New Orleans we use a modified form which we call a "Simpson-Kelly suspension." The Simpson part is the shortening of the round ligaments, bringing them through the inner inguinal ring and suturing them to the posterior surface or the undersurface of the anterior rectal sheath. We use the Kelly part in bringing the uterosacral ligaments together and suturing them to the posterior peritoneum of the lower uterine segment. This is to keep the cervix in place. For a prolapse, second or third degree, in elderly women or in women past 35, I believe that the vaginal hysterectomy is the procedure of choice. We find no difficulty in doing it; even our residents at the Charity Hospital in New Orleans, where we have an extensive service, do this operation. In the young woman we rarely do anything other than the Simpson-Kelly suspension. We have used it for the last fifteen years and have been successful with it. This procedure was used by the late Dr. C. Jeff Miller, from whom I learned it.

DR. K. M. MARTZLOFF, Portland, Ore.: I just want to ask Dr. TeLinde two questions which I think will be informative for all of us. Do you suture the transverse cervical ligaments? and Do you suture the stump of the cervix to the pubic arch between the urethra?

DR. RICHARD W. TELINDE, Baltimore: I do want to tell Dr. Gardner that never since I have been in Baltimore have I routinely used the interposition operation for prolapse. Dr. Richardson formerly did the vaginal hysterectomy for prolapse and it was dissatisfaction with the vaginal hysterectomy that made him turn to this new operation. I don't have an opportunity to follow up the Chicago vaginal hysterectomies often, but a few weeks ago I saw a woman who had had a vaginal hysterectomy in Chicago by a noted surgeon. She complained bitterly of shortening of the vagina. I have never heard of that complaint with the Spalding-Richardson operation. Dr.

Gardner asked about the postoperative course of these patients. I don't believe it is any different than that after vaginal hysterectomy. In our hundred cases, we have no mortality to date. Of course, we are sure we shall not keep that up. I have had 2 women in fairly profound shock due, I believe, to difficulties in delivering the uterus, but one might have had those same difficulties if one was doing the vaginal hysterectomy. The ultimate results were really excellent in the 33 patients whom we had back for examination about a year and a half ago; some of these had had operations done as long as four or five years before. Twenty-six of these had been done by private practitioners and the results, as far as I could see, were perfect. The rest had been done by the house staff, there was 1 that had a recurrent cystocele and 2 others failed to admit complete symptomatic relief, although anatomically the vagina seemed to be quite normal. I agree with everything that Dr. Barrett has said about hernia. This is a hernia. I neglected to say much about the perineal repair part of the operation. I took that for granted since that is an old story with most of us and time is limited. There have been no ureteral injuries in this operation in our hands. We stay away from the ureters, which are close to the uterus just about at the point where the uterine vessels approach the uterus. The uterine vessels are left intact to supply the cervical stump. Dr. Martzloff asked two questions: Do we ever bring the stump up under the symphysis? Yes, we do. When there is a large cystocele I think it is an excellent thing to do, because then one gets more of the advantages of the old interposition operation without the disadvantages. The other question was whether we ever suture the cardinal ligaments anterior to the stump. When there is a pronounced descensus I frequently do that. By so doing one can have all the advantages of the Manchester operation without the disadvantages of cutting and crushing the bases of the broad ligaments.

HIGHLIGHTS ON EPIDEMIC DISEASES OCCURRING IN MILITARY FORCES

IN THE EARLY PHASES OF THE WAR IN
THE SOUTH PACIFIC

COMMANDER JAMES J. SAPERO (MC), U.S.N.
AND
LIEUTENANT COMMANDER FRED A. BUTLER
(MC), U.S.N.

Early in 1942 American military forces began their countermove to stem the rapid Japanese advance in the Pacific. The accomplishment of this task required the military occupation of numerous widely separated tropical islands throughout a vast subequatorial region and involved the establishment of bases on islands known to be hyperendemic foci of disease. There followed, as a consequence, a series of outbreaks of tropical diseases in epidemic proportions of a magnitude and potential threat seldom if ever exceeded in American military history.

Many factors contrived to create a situation which would favor a wide-scale outbreak of disease in the very early phases of the Pacific campaign. The initial occupation, of necessity, took place with a haste which did not permit carefully considered plans of disease prevention. The newly occupied islands were known to be endemic centers of an impressive array of threatening diseases, such as malaria, dengue, dysentery, scrub typhus, yaws, filariasis, tuberculosis and leprosy. Many of these, unfortunately, were diseases presenting prob-

lems of prevention with which most medical officers were almost totally unfamiliar. In addition, in certain instances, intelligent prevention was impossible, for the mechanism of transmission was not known to medical science. Most of the diseases were epidemic in nature. They could be expected to disable large numbers of men under conditions of combat and at the very time in which control would be most difficult. Further jeopardizing disease control at first was the underlying situation, in which almost the total efforts of the newly occupying forces had to be directed toward even more urgent matters, such as obtaining food and ammunition and of digging in to fight the enemy.

A consequence of this situation was that in the early phases of the war almost all troops based in the Pacific suffered from one or more epidemic diseases. The lessons learned from these early experiences, however, were not unheeded. The end result was that, in spite of all the obstacles faced, epidemic diseases soon came under control. It is believed that history will in time show that Allied successes in disease control so greatly exceeded those of the Japanese that a major advantage in the war was thereby gained.

At present only some of the highlights of the story of the various epidemic diseases which occurred can be told. This report, in particular, encompasses only the epidemic disease experience in the South Pacific Command Area. This included New Caledonia, the New Hebrides, the Solomons, the Fiji Islands and the Ellice, Samoan and Tonga Island groups.

The epidemic diseases of most significance which plagued troops were, roughly, in order of importance malaria, dysenteries, dengue, Bancroft's filariasis, scrub typhus and infectious hepatitis. Dysentery was encountered throughout all the island groups. Dengue was widespread but was characterized by distinct, focal outbreaks. Filariasis, caused by *Wuchereria bancrofti*, appeared in epidemic form in troops for the first time in history. It occurred in significant numbers only in the Samoan and adjacent islands despite the existence of the disease in natives in almost all the island groups under consideration. Scrub typhus was confined to relatively few cases reported from New Georgia and Bougainville. Infectious hepatitis appeared with spotty geographic distribution.

MALARIA

In importance, malaria far exceeded that of any other of the epidemic diseases. The large number of individuals contracting this disease resulted from the fact that the major military engagements were fought on some of the most highly malarious islands in the world.

That the rather remarkable limitation of endemic malarious areas in the South Pacific fortunately spared many island groups the burden of malaria prevention is important to bear in mind.

The most instructive experience in the problem of malaria is the situation which occurred on one of the first occupied malarious bases in the early spring of 1942. With the unstemmed advance of the Japanese apparently greatly menacing this occupation, a rather hopelessly small American force dug in for a bitter fight. What happened to this force so far as regard malaria serves as a classic example of what may be expected to occur when effective control is lacking.

All the elements which could predispose to a serious malaria situation participated. The site chosen for bivouac areas and military activities was one well known by the residents of the island to be the most malarious spot of the entire island. Into this area of

Commander Saperio was malaria and epidemic disease control officer, South Pacific area, for period June 1942 January 1944.
Lieutenant Commander Butler was assistant malaria and epidemic disease control officer, South Pacific area, for period July 1943 January 1944, and malaria and epidemic disease control officer, South Pacific area, for period January 1944-June 1944.
This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

dense anopheline population over 500 malarious natives were also brought to provide manual labor. These natives, in close contact with the troops, constituted, as was later shown, a malaria reservoir infective to an extraordinarily high degree. Bed nets were at first not available and few other individual protective measures, which we now know to be so important, were placed in effect. Drugs for suppressive treatment had not been brought along.

While the resultant severe epidemic was in full force, new units arrived, and active methods to stop the epidemic were attempted. Again, unfortunately, the methods employed were not those which would be promising. The principle of control adopted was drainage or treatment of any observable water surface. There was no entomologist in the group to point out the essential fact that control could follow only when the anopheline's habitat was known. Thus a campaign of quartering, raking and burning of coconut half shells, a task of gigantic proportions, was undertaken, though later it was shown that the anopheline malaria vector rarely, if ever, bred in coconut half shells. Drainage of a small swamp was attempted, though again a survey at a later date showed that anophelines were not breeding in this swamp. Nearby, a small innocuous looking stream had been overlooked. Subsequent entomologic observations showed this small stream to be the anopheline reservoir for the entire valley.

In retrospect and in the light of our present knowledge, these mistakes may seem extraordinary. The fact remains, however, that this small heroic group, unaided and faced with every conceivable obstacle, was the first of American forces to face the malaria problem in the Pacific. Prior to arrival they had not even the advantage of knowing that they were going to a malarious island. Any criticism one might want to make of these pioneer experiences could be made only by those ignorant of all the facts. Their early mistakes were soon recognized, and the lessons learned provided basic knowledge by which a brilliant achievement in malaria control followed. Details of the corrective measures which were applied have been described by Butler.¹

In contrast to the near disastrous situation on the first malarious occupied island was that which occurred at the next base occupied by military forces. The commanding officer of this base had from the first the advice of a group of trained personnel regarding the pattern of the disease methods of prevention. Equally important, this command consistently followed the recommendations which were made. One of the most spectacular achievements of the malaria control group was convincing the high command that use of imported native laborers (the major cause of the epidemic on the first occupied island) would cause a far greater loss of man hours in troops due to malaria than could be gained by the presence of natives. As a result, on this base malaria never became a major military threat. The low rates achieved, in contrast to the earlier experience, should go down in the history of preventive medicine as a classic example of what may be accomplished in disease prevention. That the extremely low prevalence of malaria did not follow because of the island's being naturally less malarious has been repeatedly demonstrated. Troops maneuvering just outside the controlled, occupied area of this island have consistently encountered malaria in serious proportions.

The value of citing these experiences is obvious. They demonstrate that malaria in this part of the world, in the absence of proper preparation and knowledge of control, may neutralize a military force with much more rapidity than the Japs themselves ordinarily could hope to accomplish. Similarly, they demonstrate the converse: that malaria can be effectively controlled even in hyperendemic areas under conditions of warfare if properly approached. They bring to light the essential fact that to attain the control of malaria it is essential that the problem be given the full time attention of well qualified specialists. They demonstrate with great clarity the additional necessity of training and education of both medical and line officers to recognize this need of control. Of equal importance is the need of a keen understanding by doctor, line officer and enlisted man concerning the role of each in measures of prevention to be taken by the individual. These measures concern the regular use of bed nets, the wearing of proper protective clothing and all the other preventive methods effective only when it is the will of an individual to utilize such protection. This is a matter of "malaria discipline," in which it is the duty of medical officers to point out all available protective measures and the responsibility of unit commanders to see that the recommended precautions are universally applied.

Subsequent experiences with malaria were largely under conditions of very active combat. The next landing took place in the face of very active enemy opposition. Fortunately it was the time of the dry season, and the first cases of malaria did not appear in numbers until approximately five weeks later. This landing under combat was followed by a repetition of many of the same mistakes that were made in the first landings on malarious islands under noncombatant conditions. The outbreak threatened to become the critical factor in the success of the operation, and the military situation was probably saved by the use of atabrine.

This drug received its first and most extensive early trial in the South Pacific. Its toxicity at the time was unknown, nor could it be predicted to what extent it would fulfil its function of suppressing clinical malaria. Important lessons were soon learned. First, the drug was apparently safe to use. Secondly, while it would prevent clinical malaria when used in proper dosage, eventually there came a time when the drug had to be or was stopped in many troops. At this time the price of employing a suppressive drug instead of true preventives became evident. Benign tertian or vivax infections became clinically active following the termination of suppression which was ordered when combat activities were no longer essential. Another serious drawback in the use of the drug was that, in suppressing clinical malaria, it tended to give military commanders a sense of false security. This in turn in some cases led to neglect or delay in developing true preventive measures such as anopheles mosquito elimination, screening and individual protective measures against mosquito bites. However, the enormous benefits of the drug outweighed such considerations, and a policy of continuing all heavily infected troops on atabrine suppression while overseas has been adopted.

It is not possible to present at length the various methods which were necessary and which were introduced to meet the problems faced in the control of malaria under combat. Control and elimination of anopheles breeding areas has been developed to an amazing extent and efficient insecticides, repellents and other devices for individual and group protection have

1. Butler, F. A.: Malaria Control Program on a South Pacific Base. U. S. Nav. M. Bull. 41: 1603-1612 (Nov.) 1943

among troops in the South Pacific area in December 1942 and during the first six months of 1943.

Many of the cases came from Guadalcanal at a period when combat fatigue and exhaustion were more pronounced than at any other time during hostilities. They tended to come down at the same time and to come from the same units. There seemed to be no correlation with a history of yellow fever vaccination. The disease finally died out and, while a few sporadic cases appeared subsequently, the numbers never reached the proportions of the original epidemic.

The second disease worthy of mention, scrub typhus, or tsutsugamushi disease, appeared in only small numbers of South Pacific troops. The few cases came from the islands of New Georgia and Bougainville. On the latter island the disease was largely confined to men who had made patrols through recently occupied Jap bivouac areas. Scrub typhus in the early phases was thus numerically of little importance.

COMMUNITY HEALTH EDUCATION BY THE MEDICAL PROFESSION

FROM MEDICINE SHOW TO HEALTH MUSEUM

BRUNO GEBHARD, M.D.

Director, Cleveland Health Museum
CLEVELAND

"Physicians as good citizens and because their professional training especially qualifies them to render this service should give advice concerning the public health of the community." So states chapter IV of the Principles of Medical Ethics of the American Medical Association. How can the physicians do their share in giving such advice? In the line of personal health the good physician has done it, all the time being aware that the original meaning of the word doctor is "teacher." In our days preventive medicine is gaining more and more ground. There will still be enough to do in the line of curative medicine—as the poor, the sick ones will always be with us. But preventive medicine has demonstrated that less sickness is possible, that diseases can be prevented, that life can be prolonged, that health for the millions can be improved. Interest in public health has enormously increased among the general public. Discussions on the administration of medical care and medical insurance are the topics of the day. We cannot complain that the present generation is not interested in the affairs of personal and public health. The increasing number of books, magazines articles and films, even before the war, demonstrated this interest and, as usual, the war has increased it. Health education in schools and for adults has become an accepted responsibility of official and voluntary health agencies, but especially of the medical profession. Those who are still doubting Thomases might be referred to Dr. W. W. Bauer's article on health education in "Administrative Medicine."¹ Here he answers the question "Is health education necessary?" discusses the old misunderstanding that health education encourages self diagnosis and self treatment and countercharges the opinion that health education stimulates hypochondriac tendencies and tends to create abnormal fears. Where health edu-

cation is done wrongly or insufficiently it usually has its reason in only sporadic or badly organized efforts of our own groups. As Charles H. Mayo said, "I believe the doctors are always at fault when the public does not understand them." The American Medical Association has a great share in lay health education. In 1911 it established the Council on Health and Public Instruction, issued a handbook for health speakers in 1919 and has published *Hygeia* since 1923.

In awareness of the platform of the American Medical Association advocating "the principle that the care of the public health and the provision of the medical service to the sick is primarily a local responsibility," the Cleveland Academy of Medicine started out in 1936 with a new approach to community health education. In close cooperation with the Cleveland Health Council twenty-two civic bodies, including museums, colleges, schools and the newspapers, were invited to study the advisability "of establishing a permanent museum of health and hygiene where scientifically prepared material of a visual nature might be made available to the public at all times."

On Dec. 28, 1936 the Cleveland Museum of Health and Hygiene was incorporated, not for profit, under the laws of the state of Ohio. Out of practical reasons we are referring to it now as the "Cleveland Health Museum." The Cleveland Dental Society and the Academy of Medicine organized a membership drive under their own members. After securing about 600 prospective members who were willing to pay annual membership dues of at least \$10 but not until "the museum's trustees had declared that sufficient funds had been pledged or paid to guarantee successful operation," lay individuals of the community were approached for financial support. A suitable site was donated by Mrs. E. S. Prentiss, who also made funds available to transform the old mansion at 8811 Euclid Avenue into a modern museum.

Health museums are distinctly different from medical museums. The emphasis in medical museums is on professional training; health museums are for lay education. Medical museums feature disease; health museums aim at better health for more people understanding health at being physically and mentally "at-ease."

There are disadvantages in using the word "museum," which for so many people sounds so like "mausoleum." On the other hand, museums are recognized as places where one can get unbiased information, where nobody tries to sell anything other than the truth and as places where there is something to look at. Museums, like all health exhibits, have special advantages. The late Evert G. Rontzahn in "The A B C of Exhibit Planning," 1918, thus summarized these advantages: "Exhibits attract attention of people who would not go to a lecture or read a pamphlet or listen to a health broadcast. . . . Exhibits are quick methods of presenting a new subject or an old subject in a new form. . . . Exhibits appeal to all sorts of men, to those who read editorials as well as to those who get no further than the baseball news."

The power of visual impression has been stated best by Tennyson in Enoch Arden: "Things seen are mightier than things heard."

A museum makes people come, stop, look, listen and, last but not least, it makes them better remember what they have learned when the occasion comes for practical application.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

1. Emerson, Haven, editor: *Administrative Medicine*, New York, Thomas Nelson & Sons, 1941.

There is also no doubt that the pure existence of such an institution is a continuous admonition of the importance of health. There will always be many people who will never come inside a museum, but those we try to reach through our neighborhood and traveling exhibits, in lobbies of banks and colleges, in settlement houses and fairs, in war plants and in department stores. The organization of a museum has also the advantage of making new financial sources available for health education. As all members of the community are benefiting by improving the health status, many are willing to participate in the financing of such a museum. In the four years of our operations about \$110,000 has been made available through the generosity of approximately 900 interested persons. The museum has just received its first endowment in the amount of approximately \$400,000.

Being a museum does not mean that we restrict ourselves to the visual means as exhibits and films; all other mediums and methods of health education are used, and always organized medicine takes the responsibility for accuracy of presentation. For more than two years a weekly fifteen minute radio program has been conducted, mostly in interview form. A Sunday health column in a newspaper used material prepared by local medical and dental members until the paper shortage forced us to stop. Every year during the hay fever season a pollen count is published in all papers and mentioned on the news broadcasts of all radio stations. We are doing this not only for the benefit of the sneezers but to make the community conscious about air pollution in general.

A health museum is an ideal place to bring different groups in contact with health problems. It is obvious why Red Cross classes in first aid, nutrition and home nursing use the museum. Last year we had 520 groups, most of them adults, averaging 20 persons, and close to 300 were Red Cross groups. Other groups varied from provisional members of the Junior League to students of theology from a nearby college; from chiropodists to students of a school of embalming; from the Slovak Literary Society to the School for the Deaf. All medical, dental and nursing students from Western Reserve University have a visit to the museum included in their field trips. The medical students hear, in addition, a lecture on "The Physician as Health Educator," and they have to write a critical report which is graded. Doctors and dentists send, from time to time, specially printed invitation cards included with their monthly statements to their patients asking them to visit the museum. (By the way, our telephone number is easy to remember for our professional friends—Randolph 0606.)

We enjoy close cooperation with the health education activities of the American Medical Association. Many of their loan exhibits are on display, and nearly 2,000 written inquiries from our question box have been answered through the courtesy of the Health Education Bureau of the A. M. A. This activity should not be underestimated: it is a highly individualized form of health education, as great care is taken in answering these letters. Olesen² states the problem that "for some mysterious reason patients either ignore or hesitate to ask questions of their attending physician. In their turn medical attendants somewhat similarly fail to meet the quite reasonable question of their patients with frank, truthful and effective replies." Our experience has shown again and again that people feel their

question is not important enough to bother a physician or they do not want to reveal their ignorance to him. Sometimes, but rarely, they try to check up on the advice of their own physician.

An important activity is the classes for expectant mothers and the so-called prospective fathers, held twice weekly at the museum under the auspices of the Cleveland Child Health Association. Admission to these classes is possible only by reference from a practicing physician.

Our emphasis on lay education does not allow us to overlook the necessity for professional training. The museum offers a one to three months internship in health education. Thirty-two persons, including one from Mexico, one from Chile and one from China, took advantage of this opportunity. In 1943 we conducted a four week summer course for the graduate students of public health of the University of North Carolina. We are also anxious to train museum technicians, making our workshops available for the rehabilitation of returned handicapped soldiers.

One of the main considerations in establishing a health museum was the creation of visual teaching aids. Before the war such material was mostly imported, strangely enough, from Germany and Japan. There is no reason why this country cannot provide its own material if provisions are made for securing the necessary staff of technicians and proper methods of distribution of visual teaching material. We started in 1940 our own workshops with one artist, one technician and three WPA artists. Today our workshop activities have grown so that our duplicate traveling exhibit "Food for Health" has been shown in about thirty-six communities in fourteen different states. A Spanish edition was constructed for the Mexican government, and the Army Air Force used the exhibits in its educational program at Wright Field, Dayton, Ohio.

Regarding our own exhibits, we have divided them between two floors; the first floor deals with exhibits strictly on human biology under the titles "Man—Wonder of Life," "Man's Hand," "Man's Heart" and "Man's Head." Great care has been taken to display everything in a pleasant manner. Our second floor deals with maternal, child and dental health and with nutrition. One room is set aside for the "special exhibit of the month." No museum would be big enough to cover all the important items of personal and public health at the same time. We have therefore a new exhibit every month going with the calendar, as Health in the Summer, or with the many campaigns. During the Christmas Seal sale we have an exhibit on tuberculosis; during the March of Dimes, on infantile paralysis; in April, on cancer, for example.

We take great care in presenting the findings of medical science but avoid anything that, to a critical lay visitor, would make the museum appear as an advertising agency for the medical profession. Frankly, we have so much respect for the intelligence of our visitors—and perhaps for the effectiveness of our exhibits—that we hope the desired result of better appreciating the work of the physician will be achieved in a more indirect way.

Regarding exhibits technic, we are proud that no signs can be found which read "Please do not touch." On the contrary, we prefer three dimensional, animated exhibits with visitor's participation, popularly referred to as "push-button exhibits." The original cost of our exhibits, not including the Transparent Man, which is a loan from the American Museum of Health, is not

2. Pub. Health Rep., May 8, 1942.

more than the production cost of a good sound motion picture of twenty minutes showing time.

Four years is too short a time to evaluate our activities. We can say only that in spite of transportation difficulties we have a still increasing attendance. Last year we had about 30,000 at the museum, and approximately 750,000 saw our traveling exhibits. Requests for loan material reach us on such a scale that it will soon become impossible to grant such requests if we do not receive help from national agencies.

Practicing physicians work under great strain these days, but one should not overlook the fact that in wartime social changes on the home front occur quicker and oftener. Increased activities in health education help to win the war too. State and county medical societies might reevaluate their health education activities and study the possibilities of establishing a health museum of their own. It is a long way from the commercialized "medicine show" to the educational health museum. That it can be done and that it works has been demonstrated in Cleveland.

8811 Euclid Avenue.

ABSTRACT OF DISCUSSION

DR. W. W. BAUER, Chicago: Most people are visually minded, and therefore a picture is worth a great many words. I think the salient points about the Cleveland Health Museum are several: It is fortunate to have had a generous patroness who gave, first, the museum property, then the means for converting it into a museum and then a liberal endowment, and who also went one step further and created an incentive for good work in health education everywhere by establishing an award which is to be made annually by a committee. It is called the Prentiss Award, and it is to be awarded to health educators who have created outstanding records in health education. I think we should all be proud, as physicians, that the medical profession, through the Cleveland Academy of Medicine, has taken this leadership in health education in Cleveland. Those of us in other communities may well go back inspired to have the medical profession in those communities do likewise, because I think we are faced with the fact that, unless the medical profession seizes and exercises the leadership that rightfully belongs to it, that leadership will pass into other and less capable hands. The Cleveland Health Museum has the advantage of being a museum, not a mausoleum where dead ideas are embalmed. The Museum is distinctly alive. There are many occasions when you can go to Cleveland and meet the Cleveland Health Museum on the street, without going to 8811 Euclid Avenue, as a result of outdoor exhibits. The large number of groups that have come to visit the Museum, the diversification from exhibits and slides and films into the fields of radio and newspaper publicity, and the gearing of the Museum to the needs of the community, are all significant reasons why in four short years Cleveland Health Museum has become an institution that I am firmly convinced that community would be most unwilling to do without. Not content with being a Cleveland institution, it has become of nationwide significance because its exhibits have been used elsewhere, and because it has furnished a workshop, a laboratory, for the development of techniques in visual education. Every community of any size at all should look forward to having a health museum of some kind. This is not the first effort in the United States to establish health museums. There was one established twenty years ago or more by a young woman whose name unfortunately escapes me, but it was in one of New York's slum areas, where she had taken a typical tenement and left half of it in exactly the condition in which she found it, deplorable in every respect, but she had taken the other half of it and converted it at small expense in money, but with considerable ingenuity, into what such a tenement might have been. That was an early effort at museum in this country.

DR. CHARLES V. CRASTER, Newark, N. J.: I should like to ask Dr. Gebhard what the annual attendance is and what procedure they take to get people in to see the exhibits. It seems to be a fine idea and one particularly good for a city with a large industrial population.

MR. HOMER CALVER, New York: I should like to emphasize the great difference between a health museum and a medical museum. A medical museum, in which the exhibits are designed for the understanding and education of the medical student or the practitioner, must present its material in scientific terms and in such detail that it is not only boring, but unintelligible to the layman. In a health museum no attempt is made to make the message encyclopedic. There is a conscious effort to reduce the text to a minimum and to avoid everything but the simplest terms. I have studied health exhibits in several countries for a number of years, but I have found no successful combination of those two objectives. If you attempt to create a popular museum and a medical museum at the same time, the result is bound to be something which is over the heads of laymen and beneath the interest of the scientist. The other point I should like to comment on is the growing development of medical and public health exhibits in science museums. A public health section in a museum of science or in a museum of natural history is not a substitute for a health museum. Dr. Gebhard pointed out that they had attendance at his museum of about 30,000 people a year. But this figure fails to represent the full measure of the program. Even the 75,000 additional contacts outside the museum through the traveling exhibits doesn't completely represent the scope of a museum such as they have in Cleveland. That institution, which is tied in with the Cleveland Health Council, is a vital, active, community center for health education—a constant, throbbing center, which day in and day out carries its message of hygiene and public health to the people. That type of community program is difficult to secure where you have only a health exhibit in another museum. So I would say to any of you who may see a spark of interest in your community for development of a museum of health that every effort should be made with the cooperation of the county medical society, the health department and the voluntary health agencies to secure a separate and distinct museum of health (even though it may be small) which is a vital center for community health education.

DR. BRUNO GEBHARD, Cleveland: I am afraid that a museum of our type, and sometimes we feel we haven't even arrived at the status of a museum—that an activity of our type cannot be measured by the attendance at the central office. As of today we have loan exhibits at the Ohio State Museum, in Omaha, the Gas and Electric Company, in Oregon and in Buffalo. I don't know how many people go to see the exhibits there. In our own city it works this way: We are a member of the Health Council and we work more or less as a specialist branch in health education for all the other voluntary health agencies. For instance, the Anti-Tuberculosis League has a mass chest x-ray examination in war plants and two weeks later we move in with our exhibits on personal health and nutrition. Sometimes it is an exhibit on dental health. It is hard for us to measure our activity, and Mr. Calver is quite right: 30,000 people, our annual average might be low. Maybe we should have said 90,000, or 300,000 in a year. We don't know how good or how bad we are. Regarding the question how we get people to come to a health museum: I think we don't realize that the need for understandable information on the part of the general public is enormous. Out of our own self protection and not to kid ourselves, we have done nothing in organizing our attempts. We have never organized visits by school classes. They come on the initiative of the individual class room teacher. We have never invited any adult groups to see us. It depends more or less, as most of those things depend, on word of mouth propaganda. We have done the usual things, street car signs and a weekly calendar in the Sunday newspapers telling what is going on. We realize that public relations are nothing else than really good personal service, and if you give that to your community you will have good attendance at your museum.

THE PROBLEMS OF CANCER
BIOLOGY

R. R. SPENCER, M.D.

Chief, National Cancer Institute, National Institute of Health,
United States Public Health Service

BETHESDA, MD.

No human malady today is of greater interest to the biologist or of more concern to the public than is cancer. The appeal to lay and professional minds alike is due not only to the manifold problems involved in the prevention, control and therapy of cancer but also to the much publicized behavior of cancer cells as a ruthless group of gangsters running amuck among the orderly functioning tissues of the human economy. In the light of our present knowledge of the cancer process, this analogy is useful and not altogether inaccurate since the human gangster and the cell gangster do have something in common. Both arise as a rule under unfavorable environments.

Unquestionably, cancer has biologic attributes that set it apart from all other forms of maladjustment. It is my purpose first to set forth some of these attributes, which, I believe, give cancer research an advantageous position in experimental biology and medicine, then to outline briefly what is now being done and finally to suggest the probable plans of attack on this admittedly major health problem.

MULTIPLICITY, SPECIFICITY AND NONSPECIFICITY
OF INCITING AGENTS

No other form of human maladjustment on the physical level has such a large number and variety of inciting agents. Excluding from consideration the well established part played by x-rays, gamma rays and ultraviolet rays in the genesis of cancer, Hartwell of the National Cancer Institute has published a survey of the literature on those substances that had been tested for carcinogenic activity.¹ Data were collected on 696 different chemicals, organic and inorganic, 169 of which were reported to be carcinogenic. By including the literature since the publication of his bulletin three years ago, Hartwell has now found a total of 1,028 compounds which have been tested for carcinogenic potency and of which 284 were reported to be active.

Indeed, every cancer investigator has been impressed with the fact that active carcinogenic compounds are found in a variety of chemical classes, that substances of widely different chemical structure possess carcinogenic activity and that among substances of the closest chemical similarity one may be active and another completely inactive. To date, no invariable correlation has been discovered between molecular structure and carcinogenic activity. The carcinogenicity of a substance is known to be influenced by many factors, including the species and the genetic constitution of the experimental animals employed, the age, the sex, the diet, the physical condition of the animal, the purity of the chemical compound, the dose, the physical state of the compound, the nature of the solvent or vehicle used in administration, and the route or site of application. The value of any experimental result is dependent on the number and kind of animals used, the survival rate and the duration of the experiment. These observations seem to suggest that, although the mechanism involved in the genesis of

cancer may have a basic pattern common to all cancers, the conditions are seldom exactly the same in the development of any two.

It should also be remembered that cancer in human beings is an environmental and occupational disease to a considerable extent. Modern industry has created for man a new and artificial environment, which has brought with it a large number of industrial and environmental hazards affecting nearly every organ of the human body. Industrial medicine, aviation medicine and radiology are products of the modern era. Hueper,² who has reviewed the literature of industrial cancer, states that:

Occupational cancers are elicited by a great variety of chemical and physical agents, such as arsenic, chromates, nickel carbonyl, radium, mesothorium, asbestos, crude mineral oil, pitch, tar, soot, paraffin oil, anthracene oil, creosote, aromatic amino compounds such as aniline, naphthylamine and benzidine, benzol, ultraviolet rays, roentgen rays and rays of radioactive substances and certain parasitic worms. . . . Habits too are responsible for cancer of the mouth, lips and cheeks in tobacco smokers and betel nut chewers, for cancer of the skin of the abdominal region in carriers of certain heating appliances in Kashmir or in Japan.

The carcinogenicity of some of these substances may be questioned.

However, cancer research has by no means fully explored the great variety of environmental and occupational health hazards to which the increasing complexity of modern life exposes us. Very likely more of these will be found as factors in the genesis of cancer. The continued increase in cancer prevalence during the past three or four decades cannot be accounted for solely on the basis of better recognition of the disease, on improved diagnostic methods or on the fact that there are more people living now to the cancer age. Cancer following x-ray burns, for instance, could not have existed prior to the discovery and use of these rays. The same may be said about cases of occupational osteosarcomas in watch dial painters, caused by the ingestion of infinitesimal amounts of radium. Still another relatively new type of industrial cancer is that occurring in dye workers due to a specific compound (betanaphthylamine) and affecting a specific tissue only, the epithelium of the urinary bladder. Cancer of the lung also has been shown to be increasing over a number of years. Is this due to city soot or to exhaust gases from automobiles, or both, or to some other agent? Seelig and Benignus³ of the Barnard Free Skin and Cancer Hospital experimented with soot from the chimney of a furnace burning bituminous coal. The soot was used as bedding for mice of the Buffalo strain. Primary tumors of the lung were obtained in 8 of the 100 test mice as compared with 1 of the 50 control mice. (This work confirmed some earlier experiments of Passey.⁴)

Shimkin and Leiter⁵ of the National Cancer Institute extracted tar from chimney soot and injected it subcutaneously into mice. Sarcomas were obtained in about half the animals. Leiter, Shimkin and Shear⁶ later tested tars extracted from atmospheric dust with benzene and with ethyl ether and produced sarcomas at the site of injection in 18 of 291 mice (C3H strain) in twelve months.

4. Passey, R. D.: *Brit. M. J.* 2: 1112, 1922.

5. Shimkin, M. B., and Leiter, J.: *J. Nat. Cancer Inst.* 1: 241-254, 1940.

6. Leiter, J.; Shimkin, M. B., and Shear, M. J.: *J. Nat. Cancer Inst.* 3: 155-165, 1942.

Nettleship and Henshaw,⁷ also of the National Cancer Institute; showed that intraperitoneal injections of minimal anesthetizing doses of urethane (ethyl carbamate) repeated at weekly intervals increased the incidence of lung tumors in C3H mice from less than 5 to more than 75 per cent. Urethane is chemically related to the barbiturates, which are widely used as soporifics. Some of the latter are now being tested on mice for carcinogenic effect; but even if they are found active, one cannot assume without more direct evidence that these drugs are factors in the genesis of cancer of the human lung.

Nevertheless it may be safely stated that in no other form of human maladjustment can one demonstrate such a multiplicity of exogenous inciting agents. Some of these agents (chemical and physical) are capable of inducing the cancer process in widely different species and in different tissues of the same species. Roentgen rays, gamma rays of radium, methylcholanthrene and benzpyrene belong to this group and are considered as highly potent carcinogens. Others, such as estrone, beta-naphthylamine and *p*-dimethylaminoazobenzene, are more selective. They affect certain specific tissues primarily and only rarely cause cancer in other organs. Nothing has ever been found which has given even a hint as to how the carcinogenic process once started may be stopped or reversed. Complete destruction of all cancer cells is at present the only known method of effecting a permanent cure of cancer. Methods of prevention seem more hopeful. Whenever a new exogenous cancer inciting agent is discovered, the knowledge provides us at once with the means of developing practical protection against this particular agent. Therefore all cancers induced by exogenous agents belong definitely in the category of preventable diseases. In this connection Kennaway⁸ has recently presented data which suggest to him that the very high incidence of primary cancer of the liver found among Negroes in Africa does not appear among Negroes in the United States and is therefore not of an entirely racial character. Hence he believes that the prevalence of this form of cancer in Africa may be due to some extrinsic factor which could be identified.

Unfortunately, the high death rate from cancer is not ascribable to cancers of exogenous origin but rather to those of endogenous origin. Clinical and experimental evidence suggests that the majority of such cancers are induced by unusual and, for the most part, long standing internal environmental and biochemical imbalances. According to the 1942 census reports, cancer of the digestive organs and peritoneum not including the oral cavity accounted for 45.7 per cent of all deaths from cancer. Cancer of the breast and of the female generative tract accounted for 43 per cent of all deaths from cancer among women. Certain of these internal cancers, now thought to be due largely to endogenous conditions, may be shown later to have extrinsic etiologic factors, such as Kennaway's suggestion for cancer of the liver among Negroes.

Of the endogenous cancers, none has received greater attention experimentally than has cancer of the breast. It is now well established that the genesis of cancer of the breast in mice involves interaction among at least three factors: (1) the genetic constitution, or the hereditary susceptibility, (2) the presence of the female hormone estrone and (3) the presence of the so-called mammary

tumor inciter or "milk factor." This last mentioned factor is a labile, antigenic filtrable agent-transmissible from mother to offspring through nursing. Of course, it cannot be stated that human breast cancer is dependent on a similar set of conditions. Yet on the basis of our knowledge of breast cancer in mice at least one investigator recently advocated "that the women of families with any malignant tumors in their ancestry refrain entirely from nursing their progeny." "Artificial feeding," he advises, "should be substituted from birth for at least one generation."⁹ There is, however, considerable doubt on the part of many that such advice is warranted at this time. (The idea was first suggested by Bittner,¹⁰ who discovered the milk factor in mice.)

It may now be safely stated that at least some cancers of endogenous origin are the resultant of a complicated set of internal factors, genetic, hormonal and biochemical. However, the factors responsible for cancer of the breast may not necessarily bear any relationship to the biochemical conditions responsible for cancer of the stomach, liver, lung, prostate or other tissues. By the same token it is apparent that a diagnostic test for cancer in one organ or tissue is not likely to be effective in detecting cancer in another organ or tissue. To be useful, a diagnostic test should detect the disease in its early stages in all locations.

CANCER AS A SURVIVAL PROCESS

For the sake of clarity and for the convenience of the investigators, the causation of cancer was divided by Ewing into two parts: (1) the causal genesis of tumors, including the inciting agents leading up to the development of malignancy, and (2) the formal genesis, or the factors responsible for the nature of the cancer cell and its tendency to unlimited multiplication. I have indicated that in the causal genesis sufficient data have accumulated to make it clear that there are multiple and diverse causal conditions which probably vary for each type of cancer. This diversity of inciting causes is so apparent that some investigators consider the different types of cancer as representing different diseases.

On the other hand, the formal genesis is concerned with the nature of the cancer cell or the changes in the cell responsible for the malignant state, which changes are thought to be essentially the same regardless of the diversity of causes or the tissue of origin. The diverse inciting agents play no part in the continuation of malignancy, nor is there any relationship between the nature of the agents and the degree of malignancy, the invasiveness of the cancer cells or the final outcome. While cancer, from the standpoint of inciting agents, may justly be regarded as a whole group of diseases, it is equally reasonable to consider it a single disease from the standpoint of the intracellular change which results in the malignant state. Although the mechanism of this change is unknown, it seems reasonable to believe, from clinical observations as well as from experimental evidence derived from the study of the metabolism and enzyme pattern of cancer tissue, that the nature of the transformation from normal to cancer cells may be essentially the same in all tissues. These considerations suggest that cancer is the result of a special type of cellular adaptation which can be distinguished from other forms of maladjustment, especially from those diseases caused by specific parasites.

10. Bittner, J. J.: *Tr. and Studies, Coll. Physicians, Philadelphia* 9: 129-145, 1941.

Every one recognizes that all diseases may be considered as manifestations of cellular reactions to unusual external and internal environmental conditions. Therefore cancer necessarily falls into the same category; but there is a difference in the cancer process, which should be emphasized. In communicable diseases one observes a process of adaptation between two living variables, the mammalian cell host and the invasive parasitic agent (virus, bacteria, protozoa). In hormonal diseases (diabetes, hyperthyroidism, gigantism, Addison's disease and other diseases) and in the various avitaminoses (scurvy, pellagra, ricketts, beriberi and so on), as well as in those conditions caused by hereditary or genetic defects (hemophilia, xeroderma pigmentosa, Huntington's chorea and others) one observes conditions or processes resulting from the efforts of the organism to survive hormonal, nutritional and developmental imbalances.

In cancer too we are observing unquestionably a movement toward that universal goal of all living things, survival. In the communicable diseases the struggle for survival may end in the death of the host, the death of the parasite, the death of both or a compromise by which both host and parasite live together in symbiosis. The removal of the inciting cause in such diseases results in the restoration of normal cell states. In cancer, by contrast, the local surviving cells do not assume their normal function following continued injury but take on the properties of malignancy and become parasitic. The intracellular change culminating in cancer usually represents a process which requires a long period of time. The very shortest recorded period between the injection of a powerful carcinogenic agent in animals and the first appearance of malignant tumors was twenty-five days.¹¹ Furthermore, the pathologist can detect no discontinuity between the precancerous and the cancerous process. Even the parasitic diseases, when chronic, are thought by some to serve as carcinogenic agents. Interval exposures of experimental animals to very small doses of carcinogens have been shown to be more effective in the induction of cancers than have single large doses.¹² That the cancer cell is the result of a process of adaptation is also suggested by various observations indicating that cancer cells are tougher and have greater survival value than have the homologous normal cells.¹³ In transplantation experiments, cancer implants are seen to elicit a greater vascular bed from the host than is found following implantation of normal tissue and to assume a rate of multiplication superior to surrounding normal tissue. It is a common clinical observation that cancer tissue in the terminal stages will continue to grow and increase in weight while the rest of the body rapidly loses weight.

This concept of cancer as a manifestation of a special type of cellular adjustment (or maladjustment, according to one's frame of reference¹⁴) is set forth here because it seems to be a safe and sound, although perhaps a somewhat obvious, biologic generalization, but it serves well as an advantageous point of view from which future attacks on the cancer problem may proceed.

As far back as 1929 Ewing¹⁵ said:

We have no satisfactory proof of the nature of malignant proliferation of tissue cells. Neither have we any definite knowledge of the nature of normal growth; we merely have descriptive knowledge of the conditions under which it occurs. We know that the ovum, when fertilized, grows under certain conditions, but we do not know why it grows. I think, therefore, that the problem of the ultimate nature of the cancer process is one of those types of information which will long escape the human mind. In the present state of science, I think it is unsolvable.

We need not be quite so pessimistic today, although we believe the majority of cancer investigators feel that the carcinogenic change is related to certain fundamental life processes, (1) growth, (2) organization, (3) differentiation, (4) mutation and (5) the aging process. It has been pointed out that the same physical agents (x-rays, ultraviolet light and gamma rays of radium) that are known to increase the occurrence of biologic mutations in suitable laboratory animals will also induce cancers in animals and human beings.

On the other hand, it is only fair to state that others, especially those who advocate the virus origin of cancer, see no need to postulate a permanent and fundamental cell change as the central characteristic of the cancer cell. Rous¹⁶ in the fourth Barnard Hospital lecture said:

All in all it now seems superfluous and a bit grandiose to assume, as has been easy in the past, that the cause for the cancerous process is a secret bound up with life itself. There is no need to suppose that tumor cells are the outcome of some inherent, fundamental cell change, though this is a favorite supposition.

The term "virus" has been used to designate many different agents. It is used here in the sense of an extraneous, autonomous, invasive, filtrable, parasitic agent of submicroscopic size. If cancer is due to a virus, as here defined, we are forced to postulate an almost ubiquitous parasite or group of parasites of mammals which remain latent for the most part but which may be activated by a large number of agents or by certain disturbances of the normal biochemistry of the organism. A strikingly clearcut example of the experimental induction of cancer by the latter means is seen in the work of Woolley, Fekete and Little.¹⁷ They were able to show that a hormonal deficiency may set up internal environmental conditions which are unfavorable to the proper functioning of normal cells. When mice of the CE strain were gonadectomized at 2 days of age, carcinomas of the adrenal cortex developed. The frequency increased with age up to 1 year, when it reached 100 per cent. No such tumors were observed in normal male and female mice of the CE strain. In this instance the organism apparently is forced to adjust to a hormonal deficiency, the burden of which falls, it seems, on the cortical cells of the adrenals. The final result is cancer. A special type of adjustment: other mice strains gave hypertrophy—not cancer. When cancers are induced in this manner it does not appear necessary to assume that the activation of a latent virus is the essential factor, although it cannot be excluded completely. At any rate, no parasitic virus agent has yet been proved to be present in any mammalian cancer at all times. The work of Milford and Duran-Reynals¹⁸

14. A successful but temporary adjustment from the standpoint of the cancer cell, a maladjustment from the standpoint of the organism as a whole. The temporary adjustment can be made permanently successful for the cancer cell if man chooses to interfere by transferring the cancer cells from animal to animal indefinitely or by continuous in vitro cultivation, thus providing a suitable environment.

has shown that the same virus (Rous I) injected into chick embryos produces hemorrhagic lesions as a rule whereas in adult chickens it produces tumors. The type of lesion produced is dependent on the resistance of the host. Neoplasia results when the host is endowed with a certain resistance to the virus. Lower resistance results in destructive lesions.

The recent studies of Greenstein¹⁹ at the National Cancer Institute yield additional evidence regarding the special characteristics of cancer cells. He has shown that the enzymatic pattern among the cancers of any one species is uniform and is independent of both the etiology and the tissue of origin. In other words, his data suggest that, regardless of the inciting agents or the tissue of origin, cancers in a given species converge toward a common tissue type. Furthermore, the enzymatic pattern of a tumor tends to resemble that of the homologous embryonic tissue rather than that of the adult tissue of origin. Hence it is natural to ask whether or not cancers represent a reversion or a metabolic dedifferentiation. The tissues of benign tumors do not reveal this pattern, as far as tests have been carried.

While it is true that there is no single measurement of metabolic activity (oxygen consumption, carbon dioxide yield, anaerobic and aerobic glycolysis) characteristic of cancer cells, they possess, nevertheless, an overall pattern which also can be characterized as approaching a more primitive or embryonic type than that of the normal adult tissue. Hyperplasia of cells is observed in many noncancerous conditions, notably the infectious granulomas; but in such conditions either the host dies as a result of the infection or recovery results and all the infected cells assume normal functions. In contrast, the cancer victim succumbs not because of the activity of a demonstrable parasite but, as far as we know, death is due to excessive activity of the host's own cells.

There is more or less complete agreement that the genetic constitution of the host is a major factor in the genesis of all cancers. In no other condition does one find such a high degree of species and individual specificity. Highly inbred homozygous strains of experimental animals have long been essential tools in the study of cancer, for in such animals genetic variability is minimized, thus permitting the evaluation of the effects of nongenetic factors. Furthermore, by selecting and inbreeding the geneticist has succeeded in developing strains that have uniformly high incidences of various neoplasms such as mammary, lung, liver and even gastric tumors. Until recently, only in these homozygous strains could most tumors be maintained through transplantation, although now Greene²⁰ has developed a technique whereby he has been able so to adjust the cancer cells of one species that they grow readily in the body of a foreign species. Greene believes that the ability of cells to grow in another species may be used as a measure or criterion of their malignancy. He says "Malignancy transcends species specificity."

In concluding this brief discussion of the cancer cell, I believe that a statement made by Cowdry²¹ in 1940 is still valid. He said:

The types of malignant cells probably outnumber those of the normal cells from which they arise. To add together what are thought to be the outstanding features of all of them and to

construct a synthetic picture of what the cancer cell is like would be both unjustifiable and misleading. . . . Malignancy is a functional attribute. . . . There is no satisfactory evidence that malignant cells of man possess anything, virus or otherwise, which is wholly absent in normal cells.

According to Darlington,²²

There is nothing surprising in the fact that reproductive particles can suddenly appear in the cytoplasm by the action either of the mutafacient nucleus or of external carcinogens, nor again that such particles may either be transmissible or only transplantable.

The hypothetical "plasmagenes" as well as viruses are regarded by Darlington as cytoplasmic nucleoprotein determiners which may be stable and useful cell components in one genotype and act as destructive agents in another.

Claude²³ has pointed out that so far organic structures found to exhibit the property of self duplication have been shown to contain nucleic acid of the one type or the other, and Hargitt²⁴ feels justified in speculating that "substances containing nucleic acids or nucleoproteins are capable of reproducing themselves."

And so the search for the secret of the cancer cell must continue as one of the most important fields of experimental biology, a field which may not yield immediately a solution of the cancer problem but which will certainly add interesting and significant knowledge of living processes as by-products to our chief objective.

THE PRESENT STATUS OF CANCER CONTROL AND RESEARCH

In the United States four philanthropic foundations use their funds exclusively for the study of cancer. These foundations are (1) the Anna Fuller Fund, (2) the Finney-Howell Research Foundation, Inc., (3) the International Cancer Research Foundation and (4) the Jane Coffin Childs Memorial Fund for Medical Research. For more than thirty years the American Society for the Control of Cancer limited its activities largely to the dissemination of information about this disease. Now this organization has awakened to a fuller realization of its duties and responsibilities, has changed its name to the American Cancer Society and has launched a far broader and more ambitious program. Its new plans propose, in addition to lay and medical education, to render financial aid in support of the diagnosis and treatment of the cancer patient, to provide equipment and supplies for laboratories, clinics and hospitals, to house and care for the advanced cancer patient and to finance organized cancer research.

The University of Texas has set up at Houston a hospital for cancer research.

The University of Minnesota has established an Institute of Cancer Biology and is the first institution in the world to offer a doctorate in cancer biology.

Hahnemann Medical College in Philadelphia has a full time Department of Oncology and in this respect is unique among the medical schools of this country.

Cancer education is being extended to the curriculum of the public schools. In the summer of 1942 the New York Association of Biology Teachers adopted a new syllabus for the tenth year biology classes in schools throughout the city. For the first time the subject of cancer was included.

The federal government by an act of Congress (approved Aug. 5, 1937) created the National Cancer Institute in the United States Public Health Service. This institute is a division of the National Institute of Health. Drafted along liberal lines, the act empowers the Surgeon General, in cooperation with a National Advisory Cancer Council, to (a) conduct, assist and foster research, (b) provide training and instruction in the diagnosis and treatment of cancer, (c) provide research fellowships in the institute, (d) secure for the institute consultative services and advice of cancer experts from the United States and abroad, (e) cooperate with state health agencies in the prevention, control and eradication of cancer and (f) procure, use and lend radium to other agencies and institutions.

The National Advisory Cancer Council, created under the same act, is authorized (a) to review research projects or programs submitted to it or initiated by it relative to the study of the cause, prevention or methods of diagnosis and treatment of cancer, (b) to collect information and make it available to scientists and the public and (c) to review applications for grants-in-aid for research and to certify to the Surgeon General its approval of grants for such projects which show promise. Several such grants have been made to Barnard Hospital.

At the present time fourteen of our forty-eight states have full time divisions of cancer control. In three of these states (Missouri, New Hampshire and Vermont) the law is administered by cancer commissions, in ten (Alabama, Connecticut, Georgia, Illinois, Maine, Massachusetts, New York, Rhode Island, South Carolina and West Virginia) by the State Department of Health, in one (Texas) by the state university.

A complete state cancer control program usually provides for:

1. The establishment of tumor clinics or hospitals for the diagnosis and treatment of cancer.
2. Reporting of cancer cases by physicians, hospitals and pathologic laboratories to the division of cancer control.
3. A system of follow-up of cancer cases.
4. Pathologic laboratories for tissue diagnostic service.
5. Statistical and epidemiologic records of case reports, death reports and pathologic laboratory reports.
6. Dissemination of information about cancer to physicians and to the public.

In that phase of the cancer problem dealing with the actual care of the patient, the Veterans Administration has perhaps a greater responsibility than has any other institution. The population of cancer cases in the Veterans hospitals has been steadily rising for several years and has now reached a total of about 1,400. At the Veterans Facility, Hines, Ill., there are 500 beds exclusively for cancer patients, and a new 600 bed cancer hospital is under construction. In New York City there are 200 beds for cancer patients, in Los Angeles 125 beds, in Portland, Ore., 50 beds and in Atlanta, Ga., 50 beds. As many as 800 cancer cases have been admitted to Veterans hospitals in one month, and the average for the year 1944 so far has been well over 700 new cases per month. According to the medical director, Dr. C. M. Griffith, 4 or 5 thousand beds will be needed for cancer cases alone, when the 10 to 15 million veterans of the present war reach the age of high cancer incidence, twenty to twenty-five years from now. The concentration of these cases in large government hospitals should be a rich source of material for extensive clinical cancer studies and experimental therapy.

Increasing interest in the coordination and integration of cancer research on a national scale is evidenced

by the number of conferences held during the last few years dealing with various aspects of the problem. A conference on gastric cancer was held Oct. 11 and 12, 1940 under the auspices of the National Advisory Cancer Council at the National Cancer Institute, Bethesda, Md. The proceedings were published in the February 1941 (volume 1, number 4) issue of the *Journal of the National Cancer Institute*. This gathering was unique in that it was the first time the laboratory investigator, the surgeon, the radiologist and the pathologist were brought together to exchange ideas and experiences and to develop plans for cooperative research on gastric cancer.

In June 1942 an endocrine-cancer conference was held at Atlantic City. More recently (September 1944) a conference of parental influence in relation to human cancer was held at the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine. The difficulties and the barriers that need to be overcome in launching studies in human genetics were fully recognized. However, the conference pointed out the need for closer cooperation between those working with cancer in experimental animals and those working with human cancer as a means of suggesting problems from one field which are suitable for attack from another. It was concluded that animal experimentation had succeeded in identifying in cancer two major and interacting influences. One of these is genetic, the other nongenetic. The nongenetic influences include certain chemicals, certain physical agents, endocrine imbalance and agents sometimes present in certain body fluids. In man, some nongenetic influences have been identified and genetic influences have been strongly suggested, at least in some forms of cancer. This evidence makes it imperative that we extend our knowledge of the interaction of these two major influences to man, and in such studies it is desirable to include all types of neoplasia, benign and malignant, as well as conditions leading to either of these.

A second gastric cancer conference was held recently (Nov. 11, 1944) at Memorial Hospital in New York City. Some of the papers read and the subjects discussed were (a) Gastric Physiology in Relation to Gastric Carcinoma, (b) Experimental Gastric Cancer in Mice, (c) Metabolic Abnormalities in Gastric Cancer, (d) Disturbances of Sugar Metabolism in Gastric Cancer, (e) Chemical Changes in Gastric Mucosa, (f) Observations on Chronic Gastritis and Cancer and (g) the Occurrence of Multiple Cancers of the Human Gastrointestinal Tract. The proceedings of this conference will appear in an early issue of the *Journal of the National Cancer Institute*. In the future, conferences on the cytology of the cancer cell, on the role of radiobiology in cancer, nutrition in relation to cancer and other phases of the problem will be sponsored as the need arises.

At the present time the National Cancer Institute acts as a repository for various inbred strains of animals and numerous transplantable animal cancers. We maintain 31 transplantable tumors in mice, 3 in the rat, 1 in the guinea pig and 1 in the rabbit. There are also available 8 inbred strain of mice, 1 inbred strain of rats and 1 of guinea pigs. These are essential biologic tools of cancer research. Frequent requests are received for these materials, which are furnished, of course, free of charge.

Perhaps it is apparent now that the attack on the cancer problem requires the combined efforts of many men trained in many different branches of the basic sciences of biology, chemistry and physics.

In conclusion, I may summarize by saying that the cancer problem as seen from the federal level includes the education of the public, the postgraduate education of physicians in the diagnosis and treatment of cancer, the loan of radium to hospitals and tumor clinics, the assisting of the states in setting up full time departments of cancer control in the respective state boards of health, advice and guidance to universities and medical schools desiring to establish departments of oncology or cancer biology, the establishment of prevention and case finding clinics, grants-in-aid to various institutions and individuals for cancer research, promotion of conferences on the various phases of the cancer problem, and the continuation of long time cooperative studies in the fundamentals of cancer biology. All this can best be accomplished, I believe, through the appointment of special cooperative committees. Such committees should be selected from members of the various cancer research foundations, from the American Cancer Society, from the American Association for Cancer Research and from various other institutions that are actively engaged in cancer control, prevention, therapy and research.

The National Cancer Institute realizes that the solution of the cancer problem is not a one man or a one institution job and that under the National Cancer Act we have certain mandatory duties in cancer control. We desire to accept our share of this responsibility. Our research program in no way precludes or hampers research in other institutions. On the contrary, through the efforts of the National Advisory Cancer Council and our grants-in-aid, private research will be stimulated and encouraged.

ANESTHESIA STUDY COMMISSIONS

HENRY S. RUTH, M.D.

PHILADELPHIA

Many reasons may be presented to support the fact that the specialty of anesthesiology at the present time is an accepted and expanding field within medical practice. It is also true that many controversial aspects still exist within it. Well founded, scientific differences of opinion are healthy and thought stimulating. On the other hand, conceptions held through lack of information or experience usually prove detrimental to any movement. This is particularly true of anesthesiology, which, representing one of the more recent comprehensive branches of medicine, has not had sufficient time to fulfil more than a small portion of the possible opportunities for service. Consequently there are today more instances of inefficient application of anesthesia perhaps than of correct management. Therefore any measure which disseminates knowledge of proper anesthesiologic thought, particularly among those not actively engaged in the application of modern anesthesiology, would appear valuable to those concerned, including the profession as a whole and candidates for surgery. For these reasons a description of anesthesia study groups probably would be valuable at this time.

OBJECTS OF ANESTHESIA STUDY GROUPS

The current method of reasoning and deduction followed by anesthesiologists is not too well known outside of the specialty. The surgeon naturally desires a surgical field which facilitates his manipulations to the

fullest extent, but he should not demand a method of anesthesia in order to obtain this that would also increase the mortality and morbidity rate of his patients. He would never do so, of course, if he was aware of the potentialities involved. The internist is mainly concerned with proper diagnosis and, where surgery is indicated, the proper preoperative and postoperative care. The anesthesiologist, whose entire attention is directed to the anesthesia, is concerned with all these factors and is equipped to understand more thoroughly the effects of anesthesia on both normal and abnormal patients and their significance with regard to the postoperative course. Therefore a constant interchange of thought is indicated between surgeon, internist and anesthesiologist in the best interests of patients. Invariably this is accomplished by staff conferences. The formation of anesthesia study groups achieves the same object between institutions by a discussion of fatalities occurring from anesthesia and of other interesting anesthetic situations. A medical staff handicapped by a poor or mediocre anesthesia service may obtain much information from the opinions expressed by surgeons and internists connected with institutions where modern anesthesiology is applied and from the statements of anesthesiologists in attendance at such discussions. The number of possible variables contributing to postoperative complications is large, and, unless an anesthesiologist is present and contributes to a discussion of them, instances in which anesthesia has a direct bearing on their production oftentimes are overlooked, or, less frequently, the anesthesia may be blamed erroneously for the difficulties. In addition, no new anesthetic agent or method can be truly evaluated until a large series of administrations is consummated. Certain detrimental aspects may appear either late or early in the series. Through the discussions at study groups, all institutions participating will have the advantage of the experiences of others and will profit from them shortly after they take place.

HISTORICAL

To the best of my knowledge, the Anesthesia Study Commission of the Philadelphia County Medical Society was the first instance of the formation of a group for this purpose by a representative body of organized medicine. In 1935, at my suggestion, the Anesthesia Mortality Committee of that society was appointed. It consisted of surgeons, internists and anesthesiologists from Philadelphia to study fatalities resulting from anesthesia. The work of the committee was originally patterned after the activities of the maternal mortality committees. Blanks were formulated for reporting fatalities. Originally the fatalities studied were limited to those occurring before reaction from anesthesia was complete.

In 1937 the status of the committee was changed to that of a commission, appointive every three years, instead of annually, as before. The number of physicians on the commission was increased, and representatives of some of the surgical specialties were included. About this time we observed that fatalities frequently were not reported to us. On inquiry we learned that the phrase "before reaction from anesthesia" was either unconsciously or wilfully interpreted as "fatality resulting from anesthesia." From our activities it was evident that a material number of fatalities were being classified as sudden deaths from other causes. We therefore requested a report on fatalities occurring the day of or the day after a surgical operation. A noticeable increase in the number of reports was evident immediately.

In 1940 the name of the commission was changed to the Anesthesia Study Commission. This was proposed for a twofold purpose. When a request for a report was received from the "Mortality Commission" it appeared that some hospitals believed that the group desired to unearth incriminating information, rather than function as an educational venture. Secondly, under the former title the program of activities was limited necessarily to fatalities only. Under the title of Study Commission many interesting discussions could be held on case reports in which a fatality had not occurred but where many factors of an informative nature could be discussed concerning an administration of anesthesia following which the patient recovered. Therefore we are now active under this designation.

A similar study group was initiated in 1941 by a few Cleveland anesthesiologists titled the Anesthesia Study Commission of the Ohio Society of Anesthetists. In 1943 there was established the Committee on Anesthesia Mortality of the American Society of Anesthetists, Inc. These two groups function by mail, the former by means of mimeographed sheets to its members and the latter by publications of case reports in the News Letter of the society. Both study fatalities and complications occurring during or subsequent to anesthesia, by publishing case reports and later making known at least the more valuable comments and discussions. These types of study organizations are undoubtedly of value, but their activities are confined mainly to anesthesiologists. Their work should not be minimized and should be continued, but, at the same time, they do not offer the opportunity for exchange of thought between the various specialties of medicine.

In order to explain more fully the possible functions of an anesthesia study group, the activities of the Anesthesia Study Commission of the Philadelphia County Medical Society will be explained in some detail.

THE COLLECTION OF REPORTS

Blanks of various types on which case reports are made have steadily been used. Reports are solicited from all hospitals in the county. Members of the commission are held responsible for reports from the institutions which they represent. An attempt is made to represent the remaining hospitals by means of members of the society, not on the commission but selected by its officers, who are friendly and sympathetic toward the work. The reporting of cases, unfortunately, is on a purely voluntary basis. This system, naturally, is not entirely efficient, in that not all fatalities are made known to us. This is true especially of deaths occurring in institutions which maintain poorly conducted departments of anesthesia. These hospitals probably have the largest number of fatalities from anesthesia, and they therefore may believe that their difficulties should be concealed. On the other hand, it is those organizations which could profit to the greatest extent from the discussions. This handicap is being overcome and, we believe, will steadily diminish in the future. At the present time a growing number of instances of reportable cases from these sources is called to our attention through the efforts of certain of their own staff who are advocating an improvement of the anesthesia service or by word of mouth from other members of the profession whose interest has been stimulated by the work. Our system of reporters, unfortunately, is somewhat disrupted by wartime restrictions on the number of available interested physicians who would be cooperative, but there appears to be every reason

for the restoration of this system immediately in the postwar period, in view of the fact that it was so successful in the prewar period.

The outstanding problem militating against the greatest possible value of the study rests in the reliance on voluntary reports. Well trained and competent anesthesiologists are completely cooperative in supporting the investigation. It is natural that reports from such sources rarely constitute obvious errors—those most indicative of correction. Until some type of official pressure or further stimulation of interest is applied, this condition cannot be rectified rapidly. One solution may be offered in those states where the date of a surgical operation is included on the death certificate as well as the date of death. By means of the active support of the officers of the county medical society, the Department of Vital Statistics or similar organizations could supply the commission with the names of the patients and the institution where a fatality has occurred the day of or during a determined interval following surgical procedures. The reporter representing that hospital could then execute the reporting blank for the commission on the fatality. In some countries it is legally mandatory that these fatalities be reported.

DISCUSSION OF REPORTS

Reports are sent to the society headquarters or to the chairman or secretary of the commission. Meetings are held once a month, which meetings are open to all practicing physicians, residents and interns. One teaching institution, before the outbreak of the war, valued the activities of the commission to the extent that at least one representative of the surgical department was required to attend each meeting of the commission in order that a report might be given at the next surgical conference of that institution. Our meetings have been of sufficient value to attract numerous nonresident visitors. It is unusual for surgeons and practitioners of the surgical specialties who have once attended not to be interested to the extent of repeating their visits.

For the open monthly meetings the chairman selects the most interesting case reports and presents them from the chair. At no time does the chairman mention the name of the patient, the name of the surgeon or the name of the hospital connected with the affair. I believe that this is most important and should be followed by those who may be stimulated by this paper to initiate groups in their own localities. Exception is made only when an anesthetist or a surgeon may desire advice on a particular problem and publicly announces that the case report originated in his own practice and offers to supply further information during the discussion.

After the reading of the case report the discussion is opened to the floor. Visitors as well as members of the commission are encouraged to take part. The discussion may involve any aspect of the report. Anesthesiologists are very free in their criticism of anesthetic methods employed, but they are just as cautious in commenting on any error of surgical diagnosis, judgment or technic. This aspect of the discussion is supplied by the surgical members or visiting surgeons. If this accepted rule is not observed, the chair accepts the prerogative of maintaining the discussion within these prescribed lines. Internists contribute by making suggestions concerning preoperative, supportive and postoperative treatment. At the conclusion of the discussion a vote is taken from the members of the commission to determine, first, whether the majority believe the fatality is preventable or unpreventable, both

from the point of view of anesthesia. Only preventability from anesthesia is recorded. For example, a purely surgical death, acknowledged as such by the surgical consultants and visiting surgeons, would be classified as unpreventable from the point of view of anesthesia. If the fatality is voted preventable, a further vote is requested to decide the factors which may have initiated the death. These may include, for example, overdose or improper selection of preanesthetic drugs, an unwise selection of the anesthetic agent or method, errors in the technic in the application of the anesthetic agent, lack of or improper supportive measures during anesthesia, or improper postanesthetic care. Some instances have occurred in which it has been impossible for the commission to decide whether the fatality has been preventable or unpreventable, whereupon a request may be made for additional data.

Periodic closed meetings are held by members of the commission only, to discuss fatalities obviously preventable or unpreventable or not involving interesting and instructive aspects. Such discussions are brief, and the deaths involved are rapidly classified and recorded.

MANAGEMENT OF FINDINGS

The conclusions of the commission are recorded by the secretary. In addition, a stenographer is present at the meetings to transcribe the discussion. From these data, statistics are filed. Public reports of the commission's activities are made at intervals. A complete report, based on ten years' activities of the commission, is contemplated. This, we believe, will be informative to the medical profession in general on the problems involved in and the results of the application of anesthesia.

INTERESTING DATA ALREADY ACCUMULATED

It would seem proper at this time to call to attention some of the more interesting findings and deductions from the work of this commission. At the inception of the work of the commission, numerous statements were made to the chairman that in a medical center such as Philadelphia there would not be sufficient fatalities which could be considered entirely or partially attributable to anesthesia to occupy the attention of such a commission. Suffice it to say that in our files today we have 80 case reports as yet undiscussed, although the meetings have been held regularly except during the summer months. Since the commission was formed, of the cases classified 67 + per cent were voted as preventable and 22 + per cent as unpreventable from the point of view of anesthesia. The remainder required additional data for classification. The number of instances in which a fatality has been diagnosed as sudden death from other causes, when mismanagement somewhere along the line of anesthetic application is obvious, is indeed surprising. The stated causes in such instances are usually given as coronary occlusion, coronary embolus, cerebral embolus, pulmonary embolus or acute cardiac failure.

A common preventable cause of death was the lack of resuscitative measures or institution of ineffective ones. Numerous instances were encountered in which the patient was definitely hypoxic and oxygen was not administered to rectify the condition, or a supply of oxygen was applied to the face of a patient in respiratory paralysis, without the instituting of means of supplying oxygen to the alveoli of the lungs. Again, many times cardiac stimulants were administered to patients requiring inflations of oxygen or replacement therapy by

means of the correct indicated fluids, plasma or blood. In the hands of the uninformed, when anesthetic difficulties are encountered, intracardiac injections of epinephrine, often in overdosage, are too popular and the simple, indicated corrective measures ignored. It was the consensus of the commission frequently that, if the patient had not already succumbed, the attempted remedial measures alone would have been sufficient cause of death. It would appear that the more dramatic needles, analeptics and stimulants too often have a wider application than the indicated patent airway and simple, quiet inflations of the lungs with pure oxygen.

Preventable deaths were not uncommon because of overdosage of preanesthetic sedative drugs, errors in anesthetic judgment, improper selection of the anesthetic agent and method, tolerance of respiratory obstruction during or following anesthesia, inadequate oxygenation, especially with cardiac patients, and improper anesthetic management in general. One of the questions asked for on the report is the surgeon's diagnosis of the probable cause of death. It was interesting to note the numerous instances in which the surgeon believed the fatality was totally applicable to other causes, but the commission, unanimously and without dissension, voted the cause of death as entirely preventable from the standpoint of anesthesia.

COMMENT AND SUMMARY

The probable foremost benefit is the direction of the attention of the medical profession in general to fatalities occurring from improper anesthesia and its mismanagement, which otherwise would be considered attributable to other causes. If the inception of study groups of this character was functioning more generally, a more accurate estimate of the mortality rate from anesthetic practices could be obtained. The knowledge of basic improvements in the choice of agent, technic and general management of anesthesia, indicated resuscitative measures, and correct preoperative and postoperative care could be more widely disseminated. Finally, such group studies would encourage the keeping of more accurate anesthetic records, which to date we have found to be sadly inadequate in general but which are so necessary in determining the role played by anesthesia in the surgical mortality rate.

ABSTRACT OF DISCUSSION

FREDERICK P. HAUGEN, Philadelphia: The death of a person while under the influence of an anesthetic constitutes a major tragedy of surgery. The death may be, and frequently is, unpreventable. It is through intellectually honest discussion of the factors leading to the tragedy that progress can be made in preventing similar occurrences. Such discussion between surgeon and anesthetist may be devoid of results, for each tends to excuse or blame the other. There may be much to be learned, however, by the objective discussion of such cases by a group as has been described by Dr. Ruth. Operating room tragedies are frequently so efficiently covered up that scarcely any one outside the immediate witnesses will know of them. There are good reasons why this is done, of course, but it emphasizes the necessity for extreme tact in obtaining information for study commissions. It also emphasizes the necessity of respecting the anonymity of the principals. It is gratifying to us who are on the commission to note the interest anesthetists and surgeons have in learning the opinions on their cases, for often they will disclose their identity to clear up some point of discussion. A representative of one of the larger life insurance companies told me that his company considered that an individual undergoing surgery had one chance in four hundred of dying from the anesthetic alone. That was a rather

startling statement and quite in contrast to one by a gynecologist who expressed surprise that our anesthesia study commission would have cases to study. Probably the true figure for anesthetic deaths is somewhere between these, and it would seem that the two extremes could be brought closer together by a proper interpretation of the cause of deaths. There is a tendency to look for causes beyond temporal control, and convenient diagnoses are coronary occlusion, pulmonary or cerebral embolism, or status lymphaticus. The apparent willingness of some of the men entrusted with patients' lives to condone the conditions which permit ignorance of the fundamentals of physiology and pharmacology to expose people daily to needless risk is the disturbing feature. It offers a challenge to anesthesiologists to stimulate interest in their own communities in a study of anesthesia morbidity and mortality. To Dr. Ruth goes the credit for showing that this can be done.

DR. ROLLAND WHITACRE, Cleveland: In an effort to decrease the surgical mortality rate it has always been a common practice for anesthesiologists and surgeons to discuss the fatalities and complications resulting from anesthesia. Unfortunately the value of these discussions is limited because they are usually confined to the staff of only one institution. Other physicians do not have an opportunity to study these cases objectively because they are rarely reported in the literature. From an educational point of view this represents a tremendous waste of clinical material. As physicians interested in the progress of anesthesiology, we are greatly indebted to Dr. Ruth for organizing and putting into successful operation a method whereby an increased number of physicians can study the clinical reports of fatalities during anesthesia. Dr. Ruth's work in Philadelphia has served as a stimulus for the formation of anesthesia study commissions on a statewide and later a nationwide basis. This Study Commission of the Ohio Society of Anesthetists, which was inaugurated in 1941, has not only served as a means of disseminating information regarding problems in anesthesia but has also been an important factor in the development of an active state society devoted to the advancement of anesthesiology. Perhaps the most important function of the anesthesia study commissions is to acquaint the medical profession better with the number of complications and deaths that occur as a result of anesthesia. Because of incomplete and inaccurate records there is a prevailing impression that complications rarely occur during anesthesia. An abundance of evidence is being accumulated by the various study commissions and groups interested in keeping accurate records that this opinion is not supported by facts. Many more deaths result from improper anesthesia than is generally realized. These findings bear out the remarks made by Dr. John C. Warren in his presidential address in 1850 at the fourth annual meeting of the American Medical Association. Dr. Warren at that time, only four years after anesthesia was introduced, warned of the dangers of relegating this important service to improperly trained individuals. In the succeeding ninety years no evidence has been presented to alter this opinion.

DR. HENRY S. RUTH, Merion Station, Pa.: A project of this kind can be performed in an entirely anonymous fashion. Also it emphasizes and exposes many facts otherwise concealed. I trust that this small venture of ours may spread at least to some extent to other portions of the country.

Hospital Facilities in Formosa.—There are many government, public and private hospitals scattered throughout Formosa, but those of any considerable size are limited; only a few have a capacity greater than 80 beds. The majority of the private hospitals and clinics have 10 to 50 beds. Of the large hospitals, all except four or five are administered by the government. Taihoku is the medical and hospital center of the island and the largest and best hospitals are located there, as are a leprosarium and an institute for the control of venereal diseases. There is only one small tuberculosis sanatorium on the island. There is a medical school attached to the Imperial University of Taihoku. —Simmons, James S., and others: *Global Epidemiology*, Philadelphia, J. P. Lippincott Company, 1944.

THE THERAPEUTIC INDICATIONS OF THE SULFONAMIDES AND PENICILLIN

FRANCIS G. BLAKE, M.D.

NEW HAVEN, CONN.

The indications for chemotherapy with the sulfonamides and penicillin may be divided into those which are well established through common and consistent experience and those concerning which there is uncertainty either because of conflicting results recorded in the literature or because experience is still too limited or uncontrolled to provide a definite conclusion.

Because of the limitations of time I shall confine my remarks largely to the positive indications for the use of the sulfonamides and penicillin, avoiding discussion of debatable territory and the long list of virus, bacterial, mycotic, rickettsial and other infections in which neither the currently available sulfonamides nor penicillin are indicated.

The first and most important indication is the etiology of the infection in the patient to be treated. Factors which may modify this indication and the choice of drug to be used are the site of the infection, the nature of the pathologic process, the immediate and potential severity of the infection both with respect to complications and ultimate outcome, and, in the case of the sulfonamides, known or potential liability of the individual patient to the more serious toxic effects of these drugs.

The infections which are curable or, if not cured, favorably modified by the chemotherapeutic agents under discussion may be divided into three groups with respect to etiology:

1. Those in which both the sulfonamides and penicillin are more or less effective, though not necessarily equally so, namely certain gram positive and gram negative coccic infections: hemolytic streptococcus, pneumococcus, staphylococcus, Streptococcus viridans, meningococcus and gonococcus.

2. Those in which the sulfonamides are of value but not penicillin, namely gram negative bacillary infections such as those caused by the colon bacillus, dysentery bacilli, Hemophilus influenzae, Friedländer's bacillus and Ducrey's bacillus.

3. Those in which penicillin is of value but not the sulfonamides, namely syphilis, yaws and possibly other spirochetal infections and those due to the Clostridia—gas gangrene.

As for the first group, in the less severe hemolytic streptococcal infections in which there is tissue invasion without suppuration, necrosis or bacteremia, such as erysipelas or lymphangitis, the sulfonamides are ordinarily sufficiently effective to be indicated as the drug of choice, if for no other reason than because of simplicity of administration. The same may be said of the milder upper respiratory mucous membrane infections, such as tonsillitis or pharyngitis, although the real value of the sulfonamides in these infections is still debatable.

In the more severe hemolytic streptococcal infections with suppuration or necrosis and with or without bacteremia penicillin appears to be much more effective

Read in a panel discussion on "Chemotherapy" in the General Scientific Meetings at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 12, 1944.

and consequently the drug of choice. It often succeeds in bringing about a cure when the sulfonamides have failed. Included in this group are severe cellulitis, mastoiditis with or without intracranial complications, meningitis, pneumonia, empyema, pericarditis, endocarditis, peritonitis, puerperal sepsis, osteomyelitis, suppurative arthritis and infected wounds. In such conditions as empyema, meningitis and arthritis it must be injected locally as well as intravenously or intramuscularly.

In pneumococcic infections the sulfonamides have proved sufficiently effective in lobar pneumonia to justify their continued use as the drug of choice at the beginning of treatment, but one should be prepared to shift to or add penicillin promptly in cases that do not respond quickly to the sulfonamides. In very severe pneumonia and particularly in the aged and in other pneumococcic infections such as mastoiditis, meningitis, empyema, endocarditis and peritonitis penicillin is more effective and consequently indicated from the start.

In staphylococcic infections such as furunculosis, carbuncles, osteomyelitis, mastoiditis with or without intracranial complications, meningitis, sinus thrombosis, pneumonia, lung abscess, empyema, pyelonephritis and wound infections with or without staphylococcemia the sulfonamides, though occasionally beneficial, have on the whole been disappointing. Penicillin, on the other hand, has proved very effective in a high proportion of cases and is unequivocally the drug of choice. Failures do occur, of course, possibly because of the fact that some strains of staphylococci contain penicillin inhibitor, as recently shown by Kirby, similar in its inhibiting action to the penicillinase found in colon bacilli.

Streptococcus viridans subacute bacterial endocarditis has rarely responded more than temporarily if at all to the sulfonamides. Recent experience with large amounts of penicillin given in three to four week courses indicates that in some cases it may be effective in inducing remissions. Although much more experience is needed to define its ultimate usefulness, its trial at least is indicated.

In the two important gram negative coccic infections, *Neisseria meningitidis* and *Neisseria gonococcic* the sulfonamides have been indicated in the former that they are still indicated and penicillin should be resorted to only in those cases which fail to respond to the sulfonamides or possibly as an additive treatment in the very severe fulminant cases.

Penicillin, now demonstrated to be more effective than the sulfonamides in curing gonococcic infections, would appear to be indicated at least in all cases complicated by arthritis, ophthalmia, endocarditis, pericarditis, peritonitis, epididymitis and prostatitis and in all cases of sulfonamide resistant gonorrhea. Whether it will properly replace the sulfonamides in simple acute urethritis remains to be determined.

Of the second group of infections, in which the sulfonamides are indicated and penicillin is contra-indicated because it is ineffective, little need be said except to reiterate that they comprise a group of gram negative bacillary infections including colon bacillus infections, particularly of the urinary tract, *Hemophilus influenzae* otitis media, mastoiditis and meningitis, the bacillary dysenteries, Friedländer bacillus infections, including pneumonia and soft chancre.

Similarly little need be said of the third group, in which the sulfonamides are of little or no value and in which penicillin appears to be indicated, other than to state that the exact usefulness of penicillin in human clostridial infections remains to be determined and the final definition of its already established usefulness in syphilis will require prolonged study.

Clinical Notes, Suggestions and New Instruments

STAPHYLOCOCCUS ALBUS SEPTICEMIA FOLLOWING NEPHROLITHOTOMY

RECOVERY WITH PENICILLIN

ROBERT H. HERBST, M.D., AND JAMES W. MERRICKS, M.D., Chicago

Mortality with hemolytic *Staphylococcus albus* septicemia occurs in about 90 per cent of cases. We have not previously seen a patient survive with this type of infection. When the skin is covered with a myriad of pustules they reflect the fulminating state of the infection in every organ in the body. In a previously unreported personal case several years ago following litholopaxy death ensued although a blood sulfathiazole level of 7.5 mg. was maintained. The skin of the patient was studded with minute white pustules and at postmortem examination small collections of pus, the result of infected emboli, were found throughout the body. The present patient recovered with penicillin after having been resistant to sulfadiazine. Recovery occurred in spite of hundreds of these tiny pustules in the skin, accompanied by bilateral bronchopneumonia, toxic myocarditis, toxic hepatitis, acute glomerulonephritis and renal abscess.

Some authors believe that a blood sulfonamide level of 4 to 5 mg. is sufficient to bring about recovery from staphylococcemia. Apparently this depends on the virulence of the organism. Strains of *Staphylococcus albus* may be very resistant to chemotherapy. Varieties of *Staphylococcus aureus* showing white mutations may be difficult to treat. Our patient who recovered falls in the latter category, as cultures from his infected left kidney changed from *Staphylococcus albus* to *aureus* twice in a period of four years.

REPORT OF CASE

A man aged 37, an Italian, was admitted to the Presbyterian Hospital April 19, 1944 complaining of almost constant pain in the left flank which had been present for many months. Stones had been removed elsewhere from the left kidney nine years previously. The temperature was normal, the heart and lungs were clear, the pulse rate was 88 beats per minute, the blood pressure was 168/100. The urine was clear, with 3 to 5 leukocytes and 30 erythrocytes to a high power field, with a trace of albumin. Recent previous study of urine obtained from each kidney revealed no pus, no organisms and negative culture from the right, a few leukocytes, with gram positive cocci on stain and a moderate growth of hemolytic *Staphylococcus aureus* with white mutations, previously reported "albus" on two occasions from the left kidney. Radiographic studies of the urinary tract revealed kidney outlines of normal size and position with a large area of increased density over the left renal pelvis and multiple small areas over the upper and lower poles of the left kidney. Excretory urograms revealed good function of both kidneys, with only slight dilatation of the calices of the left kidney. Additional x-ray studies showed normal gallbladder function, negative stomach and colon. Chest fluoroscopy was negative. Stool cultures were negative. Serologic studies were negative. Blood count revealed 5,500,000 red blood cells and 7,000 white blood cells. A hemoglobin of 16.5 Gm. was found.

From Rush Medical College of the University of Illinois and the Presbyterian Hospital.

The blood nonprotein nitrogen was 31 mg. per hundred cubic centimeters, creatinine 1.5 mg. per hundred cubic centimeters and urea nitrogen 11.

At operation the kidney was difficult to free. A longitudinal nephrotomy incision was made over the upper pole, with removal of stones in that calix, while the large pelvic stone and lower pole stones were removed through a mid lower pole incision. X-ray examination of the exposed kidney revealed no stones. The kidney was closed around a soft tube with mattress sutures and a pad of fat fastened over the suture line. Although blood loss on the table was minimal, 1,000 cc. of whole blood was given postoperatively.

The temperature rose to 104 F. the first postoperative day and fluctuated from 101 to 105 F. for the next fourteen days. The patient ate and took all fluids by mouth from the second postoperative day. Throughout his hospital stay his appetite remained almost voracious, requiring heavy feedings supplementary to his regular meals. Sulfadiazine 0.5 Gm. was given every six hours the first four days, then 1 Gm. every four hours the next two days, a total of 20 Gm., when it was discontinued because the urinary output began to fall, dropping to 300 cc. on the eighth postoperative day. A few erythrocytes but no crystals were found in the urine. Blood sulfadiazine levels unfortunately were not done. Positive blood cultures of hemolytic *Staphylococcus albus* were obtained on the fifth postoperative day; the cultures turned a faint yellow a few days later. Blood nonprotein nitrogen on the tenth postoperative day was 131 mg. per hundred cubic centimeters and the patient was somewhat stuporous. Examination of the chest revealed evidence of a bilateral bronchopneumonia, the signs persisting for almost two weeks. Blood nonprotein nitrogen was 147 mg. per hundred cubic centimeters, creatinine 4.4 per cent on the eleventh postoperative day, when the temperature was 104 F.

Penicillin 200,000 units was given on the thirteenth postoperative day in 1,000 cc. of 5 per cent dextrose in isotonic solution of sodium chloride intravenously. The temperature fell from 104 to 100 F. in twenty-four hours. The first chill occurred on the third day of penicillin after 500,000 units, when a slight subicteric hue was noticed in the scleras. Purpuric spots and many pustules appeared all over the body in uneven distribution, remaining for almost a week. The patient was exceedingly apprehensive. Hemoglobin on the thirteenth postoperative day was 7.5 Gm., erythrocytes were 2,250,000 and leukocytes were 3,000. The urine showed heavy formation of albumin.

Penicillin was then continued by intramuscular and intravenous routes, depending on the patient's tolerance, averaging 150,000 units a day for the next three days; then the dosage on the seventh day of penicillin was increased to 180,000 units a day for two days, when the temperature fell to 99.6 F. From then on the dosage varied from 100,000 to 190,000 units a day. Supportive treatment included digitalis, vitamin C and blood transfusions, of which seven were given in 500 cc. amounts. The temperature first became normal on the thirty-ninth day of penicillin therapy after a total dosage to that point of 5,775,000 units of penicillin.

Although the blood culture became negative on the fifteenth day of penicillin, slight elevation in temperature with pain in the left flank continued at times until the incision was reopened on the eighty-third postoperative day. Several abscess cavities in the left kidney were broken down with the finger and drained. Daily dosage had been averaging about 60,000 units from the thirty-ninth to the forty-sixth day after starting penicillin, when the drug was discontinued (fifty-eighth postoperative day) for several days, then was administered again when fever recurred and continued for a period of fifteen days; meanwhile an aqueous penicillin solution was used for several days to irrigate the nephrostomy wound.

For five days after the renal abscesses were drained 100,000 units a day, administered in hourly doses of 10,000 units dissolved in 1 cc. of cooled isotonic solution of sodium chloride, was given. The penicillin was then discontinued after having been given almost continuously for eighty-one days with a total dosage of 8,355,000 units. The patient was released from the hospital on the one hundred and thirty-fifth postoperative day, with a left renal sinus, which six months postoperatively is practically healed.

COMMENT

It has been shown by Florey¹ and by Rammelkamp² that about 60 per cent of penicillin given intravenously is excreted in the urine within an hour. At the end of this time the concentration of penicillin in the blood is zero. Frequent reinjections are necessary to maintain an adequate blood level of penicillin. For this reason a large proportion of the penicillin this patient received was given in hourly doses by the intramuscular route between intravenous injections. In a recent editorial³ in *THE JOURNAL* penicillin excretory blockade was discussed. Simultaneous injection of 5,000 oxford units of penicillin and 30 cc. of diodrast reduced the excretion of penicillin from 60 per cent to 20 per cent in one hour. Another substance with a low toxicity, para-aminohippuric acid, also reduced the urinary output of penicillin and seems to warrant clinical trial. Our patient presented a self blockade in the form of a low renal function as revealed by the elevated blood chemistry and low urinary output at the start of the penicillin therapy. Because of this, more of the penicillin was retained in the blood stream and very possibly aided greatly in sterilizing it.

CONCLUSIONS

1. Prolonged penicillin therapy with a total dosage of 8,355,000 units undoubtedly prevented a fatal outcome in this instance.
2. Complete recovery did not occur until surgical drainage of the secondary renal abscesses was carried out.
3. Development of a successful method of penicillin blockade should reduce the amount of the drug necessary in a fulminating infection.

104 South Michigan Avenue.

SPONTANEOUS PNEUMOTHORAX PRODUCED
BY ASCENT IN AN AIRPLANE

LIEUTENANT COMMANDER HAROLD VINCENT HOLTER,
MC-V(S), U.S.N.R.

AND

LIEUTENANT ORVILLE HORWITZ, MC-V(S), U.S.N.R.

It is probable that air travel will become more prevalent after the war for persons of all ages and that such persons who may have suffered recent illness are likely to consult their physician before undertaking air travel. We believe that this report of a case of spontaneous pneumothorax in which the precipitating factor was the change of atmospheric pressure produced by ascent to 8,000 feet in an airplane, may influence the advice given to patients in this respect.

REPORT OF CASE

Pfc. E. A., aged 21, walked into sick bay on Sept. 13, 1944 complaining of pain in the upper right thorax, which had suddenly developed six days previously, while he was flying for the first time in an airplane. (The plane was a Marine "Commando" R5C, which had taken off less than an hour previously, and the altitude of flight was approximately 8,000 feet. Flying conditions were good; the air was smooth. The patient was a passenger sitting on the bucket seats attached to the side of the cargo portion of the plane, which is just behind the pilot's cock pit.) Since that time the pain had persisted. It was aggravated by walking, coughing, deep breathing or any type of increased exercise. The patient had been subject to frequent mild upper respiratory infections for some years, but there was no indication of pneumonia, pleurisy or tuberculosis in the past or family history. An x-ray film of the chest taken in September 1943 was considered negative.

Physical examination revealed a healthy appearing white man of moderate height and weight, not acutely ill but having some respiratory embarrassment. The trachea was deviated slightly to the left. There was hyperresonance and much decreased

3. Penicillin Excretory Blockade, editorial, *J. A. M. A.* 126: 369 (Oct. 7) 1944.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

breath sounds over the entire right lung area. The heart sounds were normal and the apical impulse was inside the midclavicular line.

X-ray examination of the chest on September 15 revealed about 60 per cent collapse of the right lung, as shown in the accompanying illustration. The patient was hospitalized and treated symptomatically.¹ Subsequent physical and x-ray examinations revealed increased expansion of the lung. On October 14 he was transferred from a forward area back to a U. S. Naval Hospital by means of surface craft with the following note: "Because of the condition described in this marine, who is connected with aviation, it is advisable that this man never fly again because of the danger of recurrence during flight. He is transferred to the U. S. Naval Hospital for further treatment and disposition with the recommendation that, in due time, survey from the service be definitely considered."

COMMENT

In considering the mechanism of this accident, it is probably easier to consider first the precipitating factor which is known than the predisposing factor which is questionable. Under normal conditions the pleural cavity is merely a potential space between the parietal and pulmonary pleura in which an average pressure of about 756 mm. of mercury is maintained. Again

under normal conditions the intrapulmonary pressure is kept approximately at the same level. In this case the pressure was rather abruptly dropped to about 560 mm. of mercury or by about 26 per cent, thereby creating a tendency for the lung to collapse partially. As long as the pleural cavity remained potential, this would not have been possible. But with the development of increased tendency to separate the pulmonary from the parietal pleura, a

Sixty per cent collapse of right lung

weakness in the pleura was exploited and pneumothorax occurred.

Another possibility is that a peripheral emphysematous bleb may have ruptured as the result of relative increase of pressure within the bleb itself. As far as the predisposing factors are concerned, evidence seems to point to adhesions or emphysematous blebs rather than to tuberculous infection in a large percentage of cases.²

It has lately been reported that patients with traumatic pneumothorax may be transported by air, at low altitudes, without jeopardy. In these cases the only change will be slight increase in the percentage of collapse of the lung, and, since a tear in the pleura already must exist, no further damage should be anticipated. In contrast to these individuals is the one reported in which the tear did not already exist but is merely a potential weakness which may be converted into a full tear by means of decreased atmospheric pressure.

Although no definite conclusion may be drawn from this particular case, it is our considered opinion that extreme caution should be exercised in advising patients who have had known diseases of the pleura about airplane travel.

SUMMARY

In a case of spontaneous pneumothorax the only apparent precipitating factor was the change of altitude due to ascent to 8,000 feet in an airplane.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports.

The Council wishes to express its appreciation for the valuable assistance rendered in the preparation of this report by Drs. George M. Coates, Edmund P. Fowler, W. E. Gross, Walter Hughson (deceased), Isaac H. Jones, Dean M. Liddle, Douglas MacFarlan, C. Stewart Nash, Horace Newhart, Paul E. Sabine and Burt R. Sharfy.

HOWARD A. CARTER, Secretary

MINIMUM REQUIREMENTS FOR ACCEPTABLE AUDIOMETERS

1. A clinical audiometer is an instrument for measuring at prescribed frequencies the auditory threshold of any individual in decibels referred to a standard intensity level known as the "normal threshold of hearing." This is defined as the modal value of the threshold of audibility of a large number of normal ears of persons in the age group from 18 to 30 years. The intensity of the sound produced by an audiometer when the intensity dial is set at zero for any frequency should be corresponding to the normal threshold of hearing for that frequency. The threshold of hearing of an individual ear referred to as the normal threshold and is the audiometer setting in decibels corresponding to the faintest tone signal which the person being tested reports correctly that he hears the test tone at least two thirds of the number of times it is presented to him. In applying these tests the threshold should be approached twice as often from below as above the threshold.

2. The reference standard for "Normal Ear Threshold" for air borne sound at the specified frequencies for audiometers intended for general diagnostic purposes shall be established and maintained by the National Bureau of Standards. The average sound pressure levels at these frequencies shall be those set up under standardized test procedures by three standard receivers maintained at the National Bureau of Standards when the average voltages shown below are impressed across their terminals.

Frequency of Test Tone	Voltage Level in Decibels Referred to One Root Mean Square Volt
128	— 73
256	— 88
512	— 102
1,024	— 109
2,048	— 111
4,096	— 107
8,192	— 75

These voltages were determined by comparison with the output of Western Electric 552 receivers of the Western Electric 2A audiometers.

3. *Frequency Range.*—(a) An audiometer shall be capable of producing test tones over the frequency range from 128 to at least 8,192 cycles per second. The audiometer may generate discrete frequencies or may produce continuously variable frequencies over the whole or part of this range. In either case frequencies of 128, 256, 512, 1,024, 2,048, 4,096 and 8,192 shall be producible at clearly marked and definite settings of the frequency indicator.

(b) The frequency of each of these test tones shall not in any case depart by more than ± 2.5 per cent from the indicated frequency. Dials shall be marked so that frequencies can be easily read.

4. *Purity of Test Tones.*—At 128 cycles the sound pressure level of any single harmonic in the test tones at all intensity settings shall be at least 20 decibels below the sound pressure level of the fundamental, measurement to be made on a closed standard coupler with a volume of approximately 60 cc.

At all other frequencies the intensity of any harmonic shall be 25 decibels below that of the fundamental.

5. *Intensity Range and Calibration.*—Audiometers shall be capable of producing test tones of the purity prescribed at the various frequencies and of maximum intensity levels not less than those shown:

Test Tone Cycles per Second	Intensity Level in Decibels Above Normal Ear Threshold
128...	60
256...	80
512...	85
1,024...	90
2,048...	90
4,096...	90
8,192...	70

(a) Intensity levels at the foregoing decibel settings of the audiometer shall not differ from the specified values by more than ± 25 decibels.

(b) Intensity of test tones shall be variable in steps not greater than 5 decibels, with appropriate dial markings to indicate the respective intensity levels in decibels referred to the normal threshold as zero. The difference in measured intensity levels corresponding to two adjacent settings shall not vary from 5 decibels by more than ± 1.0 decibel for any frequency.

6. Audiometers shall be supplied with bone conduction receivers for measuring the threshold of hearing for bone conducted sound.

(a) A suggested procedure for establishing the normal threshold of hearing for bone conducted sound as measured by a particular audiometer is as follows. Determine at each frequency the intensity level, as measured by the intensity setting of the audiometer, which can just be heard by each of 5 normal hearing subjects when the bone conduction receiver is pressed against the mastoid just back of the ear. The average of the five measurements at any frequency is taken as the normal threshold for bone conducted sound of that frequency. This average will be the zero setting of the particular audiometer for bone conducted sound of that frequency. A "normal hearing subject" is defined as a person between the ages of 18 and 30 whose measured threshold of hearing for air borne sounds does not depart from the normal threshold by more than ± 10 decibels at any frequency. All measurements in the foregoing are to be made in a room free from extraneous sound of sufficient intensity to vitiate the measurements. Acceptance tests on this requirement may follow the same procedure.

(b) The bone conduction receiver shall be so constructed that it does not produce sound in the air to a degree that will affect the validity of bone conduction measurements. "To test for this requirement, the bone conduction receiver is held close to but not touching the ear. The audiometer setting for minimum audible intensity under this condition should be 10 decibels higher than when the receiver is pressed against the mastoid."

7. *Inherent Noise.*—The noise level due to alternating current hum, commutator ripple or any other cause shall be so low that it is inaudible to a normal hearing person in the presence of the test tone produced at any attenuator setting at any frequency.

8. If the manufacturer supplies with his instrument charts for plotting measured hearing loss, these charts shall comply with the following specifications: The chart is to be ruled with rectangular coordinates, with frequency as the abscissas and "hearing loss in decibels" as the ordinates. Frequencies shall be shown by vertical lines spaced at octave intervals. (For an instrument that produces test tones at intermediate frequencies, vertical lines to correspond to these frequencies should appear at the proper fractional parts of the octave intervals.)

Normal hearing for both air borne and bone conducted sounds shall be indicated by a single horizontal line marked line 0, near the top of the chart. "Hearing loss in decibels" shall be indicated by equally spaced horizontal lines, spaced at 10 decibel intervals and numbered downward from the 0 line. The dis-

tance between the octave vertical lines shall be two times the distance between horizontal 10 decibel lines.

9. *Guaranties.*—The manufacturer shall make to the purchaser the following guaranties: (a) That any defect other than those due to accident or damage from improper use that may appear within a period of one year from date of purchase will be corrected and the instrument recalibrated at no cost to the purchaser except for transportation charges; replaceable parts which may deteriorate with use, such as vacuum tubes, shall, by agreement, be supplied at reasonable cost.

(b) That the maker will provide adequate instructions for the proper care and upkeep of his products and will encourage the purchaser to send his audiometer at reasonable intervals to the factory or to a qualified distributor for check as to performance and needed servicing at a reasonable cost.

10. *Marketing and Advertising.*—Rules of the Council on Physical Medicine shall be adhered to by manufacturers of acceptable audiometers.

MINIMUM REQUIREMENTS FOR ACCEPTABLE ELECTRICAL HEARING AIDS

A hearing aid acceptable to the Council on Physical Medicine shall be demonstrably capable of increasing the intensity of sound between 300 and 3,000 cycles by at least 30 decibels. Firms shall meet the following requirements:

1. Hearing aids shall have imprinted on each transmitter and air or bone conduction receiver a model number (type or class) or some equally suitable identification.

2. The manufacturer shall supply with the instrument submitted for acceptance data obtained in his own laboratory or in a recognized independent laboratory to support any specific claims which he may make for his instrument. For example, a claim for controllable frequency characteristics should be substantiated by graphs showing the change in frequency response which can be effected. He shall also supply laboratory data in the form of graphs showing the overall acoustical amplification which the instrument will give over the frequency range from 512 to 4,096 cycles, outlining the method used.

3. The manufacturer shall state the possible voltage combinations and advantages resulting therefrom together with battery drain on A and B batteries at one half, three fourths and full volume settings.

4. A hearing aid may be judged not acceptable on the basis of a high inherent noise level.

5. The manufacturer shall furnish to the Council a copy of its guaranty to the purchaser.

6. There shall accompany each hearing aid clearly written instructions for its use.

7. The manufacturer shall give evidence that adequate facilities for servicing the instrument are available and shall furnish names and addresses of servicing agencies.

8. The manufacturer shall agree to furnish from stock to the Secretary of the Council on Physical Medicine a hearing aid for inspection and test. On the request of the Secretary, the manufacturer shall supply him with an order on any of the authorized agents for an instrument for test. On the completion of tests, the instrument shall be returned complete to the manufacturer.

9. All material used in manufacture shall be of first grade and the workmanship skilfully performed. The assembly of the instrument shall be inspected by the examiner, who shall determine whether or not the workmanship has been skilfully performed.

10. The firm shall be responsible for the ethical merchandising practices, financial dealings and contracts of its agents, sales representatives and service men with the purchasers of the instruments. The standards of merchandising and the acceptability of advertising shall meet requirements of the Council on Physical Medicine.

ANTISPASMODIC ACTION OF "HYPO- TENSIVE" EXTRACTS ON SMOOTH MUSCLES

The experimental demonstration by Abelous and Bardier in 1909 that urine contains a "hypotensive" substance gave impetus to a search for tissue extracts in treatment of hypertensive and myospastic states. Two products in particular received particular acclaim both here and abroad as effective antispasmodics. The two products, known as depropanex and padutin, are pancreatic extracts free from insulin, histamine and choline. A number of clinical reports emphasize their effectiveness in the treatment of intermittent claudication, ureteral colic, angina pectoris, dysmenorrhea and peripheral arterial disease. The benefits obtained were credited to a supposed antispasmodic action associated with direct relaxation of smooth muscles in the blood vessels, ureter or uterus. These extracts were administered orally or intramuscularly, and intravenous injections were considered capable of harm.

Dreisbach and his associates¹ performed careful laboratory experiments to determine the antispasmodic action, if any, of these extracts on the smooth muscles, subjecting circular muscles of the abdominal aorta, common carotid and femoral arteries, longitudinal muscle of the small intestine, circular muscle of the ureter and strips of bladder fundus in a Locke-Ringer solution to the effect of these drugs. Concentrations of padutin over four hundred times the possible theoretical tissue levels based on clinical dosage were necessary to produce some depression of intestinal ureteral and vascular muscles, but the same effect was produced by the preservative glycerin in this product. The same was true for depropanex and its preservative, phenol, for intestinal and ureteral muscles. Depropanex, independently of the preservative, caused stimulation of arterial and bladder muscles with concentrations twenty

to sixty times the theoretical concentration based on the recommended clinical dosage. Lower concentrations were devoid of demonstrable effects. The ineffectiveness of these agents on smooth muscles is in accord with their ineffectiveness intramuscularly and orally on the circulation and with their lack of toxicity in animals, which, however, react definitely to intravenous injection, a method warned against clinically. The authors feel that the local irritating effect of the preservatives may be a possible factor in the clinical benefits derived when these extracts are injected intramuscularly. Their experimental results leave little doubt that these so-called hypotensive extracts are without demonstrable intrinsic therapeutic merit in the dosage and methods of administration recommended. These and similar extracts have not been accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

The results of these investigations are but another demonstration that clinical results, even though apparently beneficial, are not in themselves a definite proof of the effectiveness of the drug employed. The pharmacodynamic effect of a substance can with greater accuracy be demonstrated in properly controlled animal experiments.

PENICILLIN-LIKE SUBSTANCES IN HIGHER PLANTS

Demonstrations of strong bactericidal substances in certain fungi have reopened an older field of botanical investigation, search for predictable bactericidal substances in the tissues of higher plants. Several antibiotics were reported by earlier botanists. Thus, Stickl¹ showed that certain alkaloids extracted from the common celandine were bactericidal against both staphylococci and the anthrax bacillus. Jordanoff² found that extracts of *Capsicum annum* would kill several plant pathogens. Valette and Liber³ showed that convolvulin is bactericidal for pneumococci. Antiseptic properties have also been reported for raw juices of cabbages, turnips and horse radish.⁴

Systematic search for antibacterial plant extractives was first undertaken in 1942 by Osborn⁵ of the Sir William Dunn School of Pathology, Oxford University. In this search 2,300 different angiosperms (flowering plants) were tested. Selected portions of each plant were ground up by pestle and mortar with sand in a sufficient amount of distilled water to produce a smooth pulp. The pulp was strained through silk and the resulting filtrate tested against both *Staphylococcus aureus* and *Escherichia coli*. To make the tests sterile,

5. Osborn, E. M.: *Brit. J. Exper. Path.* 24: 227, 1943.

1. Dreisbach, Robert H.; Van Winkle, Walton, and Hanzlik, P. J.: *Antispasmodic Actions of "Hypotensive" Extracts on Smooth Muscles*, *Arch. Int. Med.* 74: 424 (Dec.) 1944.

filter paper disks about 1 cm. in diameter were dipped into the filtrate and then placed on seeded agar plates. The plates were inoculated at 37 C. for twenty-four hours. The diameter of the zone of complete inhibition of bacterial growth was taken as a rough index of bacteriostatic titer. Inhibition zones 20 mm. in diameter were recorded as 1 plus, 30 mm. in diameter as 2 plus and so on up to a maximum inhibition of 70 mm. in diameter (6 plus).

Out of the 2,300 plant species thus far tested, 134 species gave frankly positive results. Forty-two of these extracts gave 1 plus or 2 plus inhibition with *Staphylococcus aureus* but were completely inactive against *Escherichia coli*. Most of the others gave 2 plus to 6 plus inhibitions with both organisms. Among the most interesting were extracts of the seeds of a number of varieties of cabbage, cauliflower, broccoli or kohlrabi, which gave 2 plus inhibition with both the *staphylococcus* and *Escherichia coli*. Vegetative parts of the same plants were relatively inactive. The most potent extracts thus far produced have been from numerous species of *Ranunculaceae*. Seeds of *Clematis recta*, for example, give 6 plus reactions with both *Escherichia coli* and *Staphylococcus aureus*, an *in vitro* effect apparently superior to that of commercial penicillin.

In testing a given plant it was found desirable to use portions of all available parts—roots, stem, leaf and reproductive organs. In certain cases the bactericidal substance was found to consist of two components, an inactive precursor located in one part of the plant and an activator in another part. The degree of stability of the active substance during wilting and drying varied greatly. Dried material from some species retains full inhibitory power after being kept for one year, while other plants begin to lose the power of inhibition within two days after picking and give negative results when fully dried. Certain well known drug plants, such as *Atropa*, *Datura* and *Digitalis*, show no bacteriostatic properties. Negative results were also noted with most plants currently recommended by herbalists.

Lucas and Lewis⁶ of the State College of Agriculture, Lansing, Mich., have recently confirmed these results. Each plant sample was emulsified in four times its weight of distilled water and then strained through cotton cloth. The resulting filtrate was then tested by the plate method against *Staphylococcus aureus*, *E. coli* and two plant pathogens (*Phytomonas phaseoli* and *Phytomonas campestris*). Among their most interesting findings were detailed studies of extracts from one of the honeysuckles (*Lonicera tartarica*). Extract of the roots was highly active against one plant pathogen (*Phytomonas phaseoli*) and gave 2 plus inhibition of *Staphylococcus aureus* and 1 plus reaction against

E. coli. Extract of the scarlet berries from the same plant was wholly inactive against *Staphylococcus aureus* but gave 4 plus inhibitions with the two plant pathogens and with *E. coli*.

Lucas envisages the application of some of these inexpensive plant extracts to problems of plant pathology and food spoilage, particularly to the prevention of certain seed borne plant diseases not yet controllable. The reported success in the treatment of certain plant diseases with penicillin⁷ forms the basis for this hope. Tests of toxicity and therapeutic efficiency of these inexpensive penicillin substitutes have not yet been made on laboratory animals.

Current Comment

MEDICAL HISTORY OF THE WAR

Elsewhere in this issue (page 527) appears an announcement from the Division of Medical Sciences of the National Research Council relative to the proposed medical history of the war. The committee has decided not to proceed with the development of the history originally contemplated, as was described in an article by Dr. John F. Fulton¹ published in *War Medicine*. The original plan called for the publication of a work giving the overall picture of medicine's contribution to the war effort. This would have included volumes on medicine, surgery, pathology, treatment, the work of the civilian agencies, the Office of Civilian Defense, the Public Health Service, the nurses, industrial medicine, dentistry and similar subjects. Recently the Surgeon General of the United States Army decided to withdraw from participation in such a history; an official release pointed out that the Army Medical Department would prepare its own history of the war and that its materials would not be available for any other historical work until after the Army medical history had been published. Since the preparation of an overall medical history of the war without the inclusion of the Army experience would be essentially like playing "Hamlet" without the participation of the melancholy Dane, the action reported in this issue of *THE JOURNAL* was taken. The complete project has been relinquished. The Bureau of Medicine and Surgery of the Navy and the U. S. Public Health Service will accordingly compile separate histories. The action of the Army Medical Department will no doubt mean that many years will pass before it will be possible to assemble anything resembling a complete picture of the great and coordinated contribution to the war effort made by the medical profession of this country. The decision is the more regrettable since the public is entitled to know what the Army Medical Department, as well as the medical profession at large, has achieved during the war period. Since medicine advances on the basis of recorded experience,

6. Lucas, E. H., and Lewis, R. W. *Science* 100:597 (Dec. 29) 1944.

7. Brown, J. G., and Boyle, A. M. *Phytopathology* 43:760, 1944.
1. Fulton, J. F. *Prospectus of a Medical History of the War of 1941 to 19—*, *War Med* 2:847 (Sept.) 1942.

the War Department by this unfortunate step will seriously hinder the progress of scientific medicine in this country, and it will also deprive the public of something that should be theirs.

BACTEROIDES INFECTIONS

Bacteroides infections are not rare, as shown by the occurrence of 20 cases at the Massachusetts General Hospital during the four year period 1939-1943.¹ Organisms of the *Bacteroides* group are common inhabitants of the mucous membranes, particularly the nasopharynx, the gastrointestinal tract and the cervix and vagina. From these sites they may invade the surrounding tissue to produce localized infections. Localized infections may spread to the body cavities and to the blood with metastatic abscesses involving especially the lungs, pleural cavities, liver and large joints. The genus *Bacteroides* consists of gram negative anaerobic bacilli that do not bear spores. The simple separation of the numerous strains of *Bacteroides* into two groups has clinical value. The *Bacteroides funduliformis* group includes gram negative, strictly anaerobic bacilli, pleomorphic in size and shape. The *Bacteroides fragilis* group comprises small gram negative bacilli regular in size and shape. They are strictly anaerobic. These organisms may be easily overlooked in a routine bacteriologic study. They often require serum or ascitic fluid in the medium to promote growth. The clinical value of the grouping is that the septicemia due to the pleomorphic *Bacteroides funduliformis* group is more severe, with greater tendency to form metastatic abscesses and a higher mortality rate than is the septicemia due to the *Bacteroides fragilis* group. *Bacteroides* septicemias usually follow throat infections, otitis media, surgery or infections of the large bowel and genitourinary tract, or gunshot wounds. Clinically the onset is sudden, with frequent chills and high fever. Jaundice is frequently observed. There is moderate anemia and polymorphonuclear leukocytosis. Pus from local and metastatic abscesses is usually thick greenish yellow, is somewhat foul and contains large numbers of *Bacteroides* organisms. As in other septicemias arising from focal infections producing metastases, treatment consists in the appropriate surgery and supportive measures. Clinical evidence as to the value of the sulfonamides is not conclusive. *Bacteroides* meningitis deserves special mention, as it comprised 5 of the 20 cases at the Massachusetts General Hospital. In 4 of these recovery occurred, whereas previously all cases reported in the literature had terminated fatally. In smears of spinal fluid the gram negative bacilli were intracellular or extracellular. They could be mistaken for influenza bacilli. Repeated anaerobic cultures were made and the *Bacteroides* organisms identified. Early and adequate spinal drainage, repeated lumbar punctures, the use of intravenous fluids and transfusions appeared to be major factors in recovery. In 1 case, however, sulfadiazine caused a prompt improvement each time when administered for three separate episodes of meningitis.

RENAL COMPLICATIONS IN SULFONAMIDE THERAPY

Renal complications continue to be reported in sulfonamide therapy in spite of the use of improved forms of the drug. Observations by Prien¹ on 2 cases of sulfathiazole anuria and uremia confirm the opinion of Long and his associates² that the sulfonamides can cause a true toxic injury to the kidney tubules independent of any tubular obstruction by sulfonamide crystals. Kidney tissue removed at biopsy (2 cases) and fresh kidney tissue obtained post mortem (1 case) were prepared with special technic to prevent the loss of any crystals. Only focal tubular degeneration was observed microscopically. Crystals or concretions were not seen microscopically or grossly anywhere in the urinary tract in the 1 case examined post mortem. In these 2 cases pathologic and clinical evidence indicated neither that sulfonamide crystals were present and washed out of the kidney before the tissues were taken for study nor that the kidney changes were of a non-specific nature and due to the disease under treatment. Prien suggests a primary chemotoxic cause for the focal lesions in the kidneys. He considers a low urinary output as the most important factor in the causation of kidney complications, but the relationship between cause and effect is not clear. Recovery in 1 case occurred apparently as a result of polyuria following decapsulation: the biopsy specimen removed at the time of decapsulation, however, showed the involved tubules to be in an almost healed stage. In the mechanism of the obstructive type of sulfonamide anuria two physical conditions are of importance. The slowing of the urine stream where the collecting tubule enters the calix tends to cause the sulfonamide crystals (first formed in the convoluted tubules) to separate out, building up a "delta of crystals" in the calix. The tubules then fill with crystals in a retrograde manner. There were rarely crystals in the collecting tubules or at a higher level unless the terminal portions of these tubules also were filled. The affinity of crystals for one another led to the formation of concretions in stagnant urine with subsequent blocking of the urinary tract.

ANESTHESIA STUDY COMMISSIONS

On page 514 of this issue appears a paper presented before the Section on Anesthesiology at the Chicago session of the American Medical Association. Following the reading of that paper and at the same session the House of Delegates adopted a resolution urging the formation of anesthesia study commissions within the state, county and other medical societies similar to that described. The need for such study is particularly acute because of the large number of new anesthetic drugs and methods introduced to the profession during recent years and consequently for the more rapid and accurate evaluation of these new anesthetic methods and practices.

MEDICINE AND THE WAR

ARMY

AIR EVACUATION BY THE AAF

An estimated 700,000 sick and wounded patients of the American and Allied forces have been transported by the Army Air Forces in all theaters of operations since air evacuation became a military necessity in 1942, it was announced by Major Gen. David N. W. Grant, the Air Surgeon. More than 525,000, or 75 per cent, of this total were transported in 1944, with the Ninth and Twelfth Air Forces carrying the larger part of the increased traffic as the result of the offensive in western Europe.

Approximately 57 per cent of the 1944 total has been Army Ground Forces and Army Service Forces personnel, 28 per cent British and other Allies, 5 per cent Navy and Marines, 7 per cent Army Air Forces and 3 per cent prisoners of war and civilians. Thus all arms and services have benefited both in health and in morale by the Air Surgeon's recommendation in 1942 that unarmed cargo airplanes be equipped with removable litter supports and be staffed by flight nurses and enlisted technicians to provide a method for the quick, safe and comfortable evacuation of casualties. The medical risk involved may be observed from the extremely low death rate in flight of 7 per hundred thousand patient trips. This record has been achieved despite the large number of critically wounded evacuated from Burma, France, Italy and the Central Pacific.

The great majority of the total patients have been flown from forward areas to base hospitals in theaters of operations, where Troop Carrier Command aircraft often have been the only practical means for safe and rapid evacuation of casualties on a mass scale. At the same time the number of patients evacuated by the Air Transport Command from the theaters into the United States increased nearly 1,000 per cent. The 1943 total was approximately 3,000 compared to an estimated 30,000 for 1944. ATC air evacuation from ports of debarkation to army general hospitals in the interior increased in similar proportions after the introduction of this method of relieving debarkation hospitals and hospital trains early in 1944.

The first known plan to transport patients by airplane was proposed by Capt. George H. R. Gosman, M. C., Army Medical Corps, and Lieut. A. L. Rhoades, Coast Artillery Corps, in 1910, after they had built an airplane at Fort Barrancas, Fla. Credit for the air evacuation of the first patient in the United States probably belongs, however, to Major Nelson E. Driver, Medical Corps, and Capt. William C. Ocker, Air Service, who in 1918 converted a JN-4 airplane into an airplane ambulance at Gerstner Field, Lake Charles, La.

While light airplanes were used extensively for the transportation of the sick and injured prior to World War II, the first mass air evacuation in American military transport airplanes probably occurred in Java and Burma in March 1942. In Burma, ten C-47s of the Army Air Forces evacuated 1,900 sick and wounded soldiers and civilians from Myitkyina to Dinjan in one ten day period of April 1942. Twenty-four litters were roped in tiers in each airplane, but the greatest number evacuated in any one airplane, counting the ambulatory, was 74.

On the basis of recommendations made in 1940 by the chief of the Medical Division, Office, Chief of the Air Corps (now the Air Surgeon, Hq. AAF), the War Department authorized the Medical Air Ambulance Squadron table of organization on Nov. 19, 1941. The medical personnel, including flight surgeons, flight nurses and enlisted technicians, were activated for the first air ambulance unit at Fort Benning, Georgia, in May 1942. Owing to the shortage of airplanes and the pressing need for transport airplanes capable of mass patient movement, the Air Surgeon then recommended that troop and cargo airplanes be utilized on return trips from the front for the secondary mission

of casualty evacuation, thus abandoning the concept of a single purpose air ambulance. In October 1942 the airplane ambulance unit was moved from Fort Benning to Bowman Field, Kentucky, and directed to train medical air evacuation transport squadrons for the care of patients in flight. The training group was subsequently designated as the AAF School of Air Evacuation.

Meanwhile mass air evacuation had become a military necessity in the New Guinea and Solomon Island counteroffensives beginning in August 1942. Flight surgeons were directed to improvise air evacuation service from available medical personnel in tactical units, and this was done with great success. Air evacuation in New Guinea was carried out by the Fifth Air Force and in the Solomons by the South Pacific Combat Air Transport Command comprised of Navy, Marine and Thirteenth Air Force units.

The first two medical air evacuation transport squadrons were activated at Bowman Field in December 1942 and entered service overseas in February 1943, one with the Thirteenth Air Force and the other with the Twelfth Air Force in North Africa. Since that time the AAF School of Air Evacuation, which became the Air Evacuation Section of the AAF School of Aviation Medicine at Randolph Field, Texas, in October 1944, has trained thirty-one squadrons. The number of flight nurses trained totals approximately 1,220, including several hundred who were not placed on, or are no longer on, flying duty. Nurses of the United States Navy and foreign governments have attended the school.

Approximately ten flight nurses have been killed in air evacuation service, seven in aircraft and three in jeep accidents. A comparable number of medical flight technicians have been lost. A large number of AAF air evacuation personnel have been cited for distinguished or meritorious achievement either as individuals or as units.

As an indication of the theater recognition of air evacuation, Major Gen. Paul R. Hawley, chief surgeon of ETO, commended Major Gen. Paul L. Williams, commanding general, Ninth Troop Carrier Command, on Sept. 28, 1944 as follows for a special assignment of airplanes to evacuation:

I want to thank you personally, and in the name of thousands of wounded American soldiers, for the great help you have given the medical service through this campaign, but particularly during the past ten days.

One week ago there were more than 7,000 wounded American soldiers awaiting evacuation from the First and Third armies. The withdrawal of air lift for airborne operations had thrown the entire load on ground transport, which could not cope with the situation. . . . You [have] saved many lives and prevented an enormous amount of suffering during this emergency.

24TH GENERAL HOSPITAL AWARDED FIFTH PLAQUE

The 24th General Hospital, created in New Orleans by Tulane University of Louisiana School of Medicine, was recently awarded the fifth Army Plaque and Clasp for exceptionally meritorious performance of duty in the Italian war theater. According to the citation accompanying the award, "this organization provided superior medical attention to thousands of Fifth Army troops. The 24th General Hospital maintained highest standards of professional treatment despite heavy emergency demands which were made repeatedly. The noteworthy accomplishment of this hospital reflects the high traditions of the Medical Corps of the United States Army." The hospital unit is commanded by Colonel Walter C. Royals, formerly of New Orleans, who graduated from Tulane University of Louisiana School of Medicine in 1917. Most officers of the unit are former faculty members or graduates of Tulane, and the majority of its nurses formerly practiced at either Charity Hospital, New Orleans, or Touro Infirmary in the same city.

ARMY RETAINS GENERAL MARIETTA

Major Gen. Shelley U. Marietta, who recently reached the statutory retiring age, will be retained by the Army as commanding general of Walter Reed General Hospital, Washington, D. C. When General Marietta was assigned to Walter Reed Hospital in 1939 there were available only 1,200 beds; now there are 3,502. His insistence on the latest modern equipment has made Walter Reed probably the best equipped hospital in the United States, if not in the world. General Marietta graduated from the University of Illinois College of Medicine, Chicago, in 1909. He received a reserve appointment in the Army in 1910, and two years later he was commissioned in the Regular Army and graduated from the Army Medical School, Washington, D. C.

ARMY NURSES GIVEN COURSES IN ANESTHESIA

A number of nurses with the 280th Station Hospital in France have been taking courses in anesthesia. Lectures and demonstrations have been given by Major Joseph Dusard, Bedford, Ind., of the surgical staff, and 1st Lieut. Bernice Boman, chief nurse of the operating room, which cover every aspect of the subject. Among the topics covered in the course are the use of the various anesthetic preparations and their actions: ether, gas-oxygen, gas-oxygen-ether, sodium pentothal and spinal anesthetics, position of patients on the operating table, preanesthetic care, shock, and the anatomy and physiology of circulation and respiration. Special technics are studied in detail.

FLIGHT NURSES GRADUATE

Twenty-three officers of the Army Nurse Corps recently graduated as "flight nurses" from the Army Air Forces School of Aviation Medicine, Randolph Field, Texas. The course for flight nurses extends over a period of nine weeks, which is divided into three phases of three weeks each. The first phase is a review of various medical and military subjects required of all medical personnel. The second phase is concerned with material peculiar to air evacuation and the third phase is occupied by actual evacuation flights within the zone of the interior.

RED CROSS BUTTON

The Red Cross button which was worn by Miss Clara Barton, founder of the American Red Cross, has been conferred by Former President Herbert Hoover on Col. Florence A. Blanchfield, chief of the Army Nurse Corps. The button, which was found among the possessions of the late Mrs. Hoover, was presented to Colonel Blanchfield at a recent meeting of the National Nursing Council in New York, in accordance with Mrs. Hoover's expressed wish and believing that the button should be the property of the head of the Nurse Corps which looks after the wounded and sick in uniform.

FIRST PHYSICIAN TO REACH LEYTE

Lieut. Herbert Karol, formerly of Chicago, was recently reported to have been the first American physician to arrive on the island of Leyte during the American invasion. He was awarded a citation for caring for the wounded on shipboard during the invasion, during heavy bombing attacks. Dr. Karol graduated from the University of Illinois College of Medicine, Chicago, in 1942 and entered the service Aug. 1, 1943.

PROMOTIONS IN THE ARMY MEDICAL DEPARTMENT

The following promotions to the rank of brigadier general (temporary) were recently announced by the War Department:

Col. Charles B. Spruit, Carlisle Barracks, Pennsylvania.
Col. William A. Hagins, Oliver, Ga.
Col. Robert C. McDonald, Washington, D. C.

ARMY AWARDS AND COMMENDATIONS

Major John A. Growdon

Major John A. Growdon, formerly of Kansas City, Mo., was recently awarded the Bronze Star "for meritorious service in connection with military operations against the enemy as General Surgeon, 3d Auxiliary Surgical Group, from June 7, 1944 to Nov. 21, 1944 in France, Belgium and the Netherlands. Major Growdon performed surgical operations two hours after wading ashore on June 7, 1944 and continued his skilful medical pursuits throughout the entire night despite numerous difficulties. Since his arrival on the continent, Major Growdon has administered his duties in an outstanding manner, thus reflecting credit on himself and the military service." Dr. Growdon graduated from Washington University School of Medicine, St. Louis, in 1935 and entered the service in August 1942.

Captain John R. Matthew

The Bronze Star was recently awarded to Capt. John R. Matthew, formerly of Knox, Ind., for "meritorious service in connection with military operations against an enemy of the United States, in France, from July 15 to Sept. 17, 1944." A censored report from headquarters in France stated that this was the period when his infantry was engaged constantly with the enemy and that Captain Matthew worked constantly, skilfully ministering to injured soldiers and enabling many men to return to further service. Dr. Matthew graduated from Indiana University School of Medicine, Indianapolis, in 1933 and entered the service May 2, 1942.

Lieutenant Colonel John V. Belmonte

The Silver Star was recently awarded to Lieut. Col. John V. Belmonte, formerly of Chicago, for performing a successful field operation at night with only a flashlight for illumination. Commander of the American Division's medical battalion, he voluntarily accompanied infantry assault troops in an advance against enemy positions to perform the operation under enemy fire. Dr. Belmonte graduated from Loyola University School of Medicine, Chicago, in 1932 and entered the service March 5, 1941.

Captain Henry Clay Robertson Jr.

Capt. Henry Clay Robertson Jr., formerly of Charleston, S. C., was recently awarded the Oak Leaf Cluster in Germany for meritorious conduct on the field of battle. It was indicated that this was during action in the Hurtgen Forest early in December. Dr. Robertson had already been awarded the Bronze Star (*THE JOURNAL*, Feb. 3, 1945, p. 281) in October during the Brittany campaign. He graduated from the Medical College of the State of South Carolina, Charleston, in 1935 and entered the service July 23, 1942.

Major Patrick H. Hoey

Major Patrick H. Hoey, formerly of Scarsdale, N. Y., was recently awarded the Bronze Star for "meritorious achievement in the performance of outstanding services" at a B-24 Liberator heavy bomber station in England, where he is group flight surgeon. Dr. Hoey graduated from Tufts College Medical School, Boston, in 1935 and entered the service Oct. 15, 1940.

Colonel Harry G. Armstrong

The Legion of Merit was recently awarded to Col. Harry G. Armstrong, formerly of Washington, D. C., for exceptionally meritorious conduct in the performance of outstanding services from Sept. 8, 1939 to June 20, 1941. Dr. Armstrong graduated from the University of Louisville School of Medicine in 1925 and entered the service Feb. 24, 1930.

Major Edgar Ross Kyger Jr.

Major Edgar Ross Kyger Jr., formerly of Kansas City, Mo., and now executive officer of a medical unit in Belgium, was recently awarded the Bronze Star for meritorious service. Dr. Kyger graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1936 and entered the service July 1, 1942.

NAVY

U. S. S. HIGBEE COMMISSIONED

For the first time in history the U. S. Navy has placed in commission a vessel named in honor of a navy nurse. The ceremony took place at Boston Navy Yard February 1, when the U. S. S. *Higbee* was commissioned. Launched at Bath, Maine, Nov. 12, 1944, the ship was christened in honor of Mrs. Higbee, second superintendent of the U. S. Navy Nurse Corps (1911-1922), one of four women to receive the Navy Cross and the only woman to receive it during her lifetime. The citation for her World War I service reads "for distinguished service in the line of her profession, and unusual and conspicuous devotion to duty as superintendent of the Navy Nurse Corps."

NEW APPOINTMENT

Capt. Waltman Walters, formerly of the Mayo Clinic, Rochester, Minn., who recently returned from a tour of duty in the South Pacific area, has been appointed chief of surgery for the U. S. Naval Hospital at Philadelphia. Dr. Walters graduated from Rush Medical College, Chicago, in 1920 and entered the service July 1, 1942.

LIEUTENANT BELTON ALLEN BENNETT JR. MISSING IN ACTION

Lieut. Belton Allen Bennett Jr., formerly of Bethlehem, Pa., has been reported missing in action. Dr. Bennett graduated from the University of Virginia Department of Medicine, Charlottesville, in 1938. He left Bethlehem in September 1943 for active service in the U. S. Naval Reserve and was later assigned to a destroyer.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Virgil Duncan Shepard

Lieut. Virgil D. Shepard, formerly of Rochester, Minn., was recently awarded the Silver Star Medal "for conspicuous gallantry and intrepidity as surgeon attached to C Company, Third Medical Battalion, Third Marine Division, during action against enemy Japanese forces in the Solomon Islands area from Nov. 1 to Nov. 26, 1943. Within twenty-four hours after our forces landed on Bougainville Island Lieutenant (then Lieutenant, Junior Grade) Shepard skilfully performed many major surgical operations despite hostile air attacks and a constant barrage of machine gun and mortar fire. Working with brilliant initiative and cool courage throughout numerous hazardous engagements, he ministered untiringly to marine wounded, often forced to operate by lantern light during hours of darkness and on one occasion with shell fragments flying through the hospital tent. Lieutenant Shepard's great personal valor and unswerving devotion to duty inspired his comrades to carry on despite extreme peril, and his outstanding professional ability contributed to the saving of many lives which otherwise might have been lost." Dr. Shepard graduated from the University of Michigan Medical School, Ann Arbor, in 1936 and entered the service Oct. 12, 1942.

Lieutenant Commander Edward C. Klein Jr.

Lieut. Comdr. Edward Caffron Klein Jr., formerly of East Orange, N. J., was recently awarded the Legion of Merit aboard the flagship of Rear Admiral Daniel Barbey for prolonging the life of a dying Japanese prisoner. Dr. Klein graduated from Columbia University College of Physicians and Surgeons, New York, in 1923 and entered the service July 1, 1944.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

U. S. Naval Hospital, Corona, Calif.: Comparison of Protozoal and Bacillary Dysenteries, Dr. John Kessell, March 22.

A. A. F. Regional Hospital, Santa Ana Air Base, Santa Ana, Calif.: Plastic Surgery, Lieut. Comdr. G. H. Gray and Dr. William S. Kiskadden, March 20.

Station Hospital, March Field and Regional Hospital, Camp Haan, Riverside, Calif.: Psychosomatic Medicine, Dr. Henry Douglas Eaton, March 20.

Torrey General Hospital, Palm Springs, Calif.: Penicillin: Recent Developments in Surgical and Public Health Antiseptics, Dr. Frederick Moore, March 20.

U. S. Naval Hospital, Long Beach, Calif.: Diabetes, Drs. J. W. Sherrill and Howard F. West, March 17.

U. S. Naval Hospital, Santa Margarita Ranch, Oceanside, Calif.: Blood Plasma and Substitutes: Water Balance, Lieut. Col. R. N. Jones and Major Edward Schwartz, March 8; Thoracic Surgery, Dr. John Jones and Lieut. Comdr. J. E. Dailey, March 22.

Station Hospital, Camp Stoneman, Pittsburg, Calif.: Infectious Diseases, Dr. Henry D. Brainerd, March 10; The Clinical Aspects of Allergy, Dr. Albert H. Rose, March 17.

Pennsylvania

U. S. Naval Hospital, Philadelphia: Surgical Technic in Acute Appendicitis, Dr. George Muller, March 23.

Virginia

Station Hospital, Fort Belvoir, Virginia: General Principles of Plastic Surgery, Dr. Robert E. Moran, March 12; Seasonal Hay Fever, Dr. Grafton Tyler Brown, March 26.

West Virginia

Ashford General Hospital, White Sulphur Springs, W. Va.: Clinic in Orthopedic Surgery, Dr. Custis Lee Hall, March 10.

NATIONAL RESEARCH COUNCIL'S PROJECTED MEDICAL HISTORY OF THE WAR

The comprehensive Medical History of the War, planned under the auspices of the National Research Council as announced in *War Medicine* for September 1942, cannot now be undertaken. The Office of the Surgeon General of the Army published the following statement in the *Bulletin of the U. S. Army Medical Department* for October 1944: "Although the Surgeon General appreciates very much the unselfish interest and efforts of the many patriotic physicians and scientists in the development of the National Research Council program, he has expressed the opinion that it should be radically revised to eliminate all accounts of Medical Department activities in this war, until such experience has been published in the official (War Department) history."

Since it would be impossible at this time to prepare an adequate, well rounded history without access to army material, the council now proposes to limit its medical history to a record of the activities of the Division of Medical Sciences during the war period. Plans for the division's history have been formulated and are being developed by the subcommittee on historical records acting through the division's committee on information.

The various services and agencies which had expected to participate in the history have been notified of the council's decision, and the majority of them plan to draft their own histories independently.

U. S. TYPHUS AGENCY ESTABLISHED AT BELGRADE

A U. S. typhus commission has been established at Belgrade at the invitation of Marshal Josip Broz-Tito. The commission will be headed by Brig. Gen. Leo A. Fox, who said that though there was no typhus epidemic in Yugoslavia there was definite incidence, especially in Bosnia.

ORGANIZATION SECTION

Council on Medical Service and Public Relations

REGIONAL CONFERENCES DISCUSS MEDICAL PROBLEMS

A series of regional conferences are being held by the new Council on Medical Service and Public Relations of the American Medical Association. Four of these conferences already have been held in Cincinnati, Washington, Kansas City and Atlanta, with three more scheduled for April on the Pacific Coast and in the other Western states.

Originally these conferences were designed to be fact finding rather than fact giving. They have developed into orientation courses for the attending physicians, state society officers, members of the Board of Trustees who have been present and most of all for the members of the Council themselves. Similar programs have been arranged for each conference, but each meeting has developed its own pattern of pertinent and pointed discussion.

CINCINNATI CONFERENCE

At Cincinnati where the conference was held for the Ohio, Kentucky, Indiana and West Virginia physicians on Oct. 29, 1944, principal interest centered around prepayment medical service plans. This conference, the first formal one to be held by the Council following an informal meeting for the New England states at Boston passed a resolution stating:

There should be advice and help coming from a central location to the state societies and the county societies having to do with their activities and solutions pertaining to medical practice.

This conference was attended by some ninety physicians. Dr. Edward J. McCormick of Toledo, Ohio, vice chairman of the Council, presided while three members of the Board of Trustees, Dr. James Bloss, Huntington, W. Va., Dr. E. L. Henderson, Louisville, Ky., and Dr. R. L. Sensenich, South Bend, Ind., were present. Among the speakers were Mr. J. W. Holloway Jr., then acting secretary of the Council, who spoke on the activities of the Council and Dr. Joseph S. Lawrence, director of the Washington Office of the Council, who told of his work in Washington. Discussion from the floor was led by Dr. L. Howard Schriver, the president of the Ohio State Medical Association, who spoke of the need for interstate cooperation as a solution for the stream pollution program particularly affecting the states bordering on the Ohio River—Ohio, Indiana and Kentucky. He also talked of the necessity for doctors to be "positive" and not "passive" in their approach to problems of medical economics and education. Dr. R. E. S. Young of Columbus, Ohio, discussed the possible pitfalls of medical service plans. Mr. Charles Nelson, executive secretary of the Ohio State Medical Society, related the action taken by the council of the Ohio State Medical Society recommending the creation of an insurance company to write health insurance on a cash indemnity basis. He explained that this company would be operated by members of the Ohio State Medical Association but would be entirely separate from the association. Dr. N. K. Foster, Hammond, Ind., president of the Indiana State Medical Association and Dr. O. O. Howard, chairman of the Study Committee on Prepayment Insurance of the Indiana State Medical Association, and Dr. A. M. Mitchell of Terre Haute discussed the action of the house of delegates of that association in regard to the establishment of a prepayment medical service plan in Indiana. Representatives from West Virginia reported that a permissive act was passed several years ago by the West Virginia legislature giving the West Virginia State Medical Society the right to sponsor nonprofit prepayment insurance plans in that state. Insurance plans are being established in accord with the act, and a rapid expansion of the program throughout the state is anticipated.

Dr. Philip E. Blackerby, secretary of the Kentucky State Medical Association, stated that the Kentucky profession is

somewhat confused in regard to the problem of health insurance and asks that the Council formulate a basic program to be translated into state programs.

Among those who took part in the discussion were Dr. Walter E. Vest, Huntington, W. Va., editor of the *Journal of the West Virginia State Medical Association*, Dr. Jonathan Foreman, Columbus, Ohio, editor of the *Journal of the Ohio State Medical Association*, Dr. A. A. Brindley, Toledo, Ohio, Dr. Barney J. Hein, Toledo, Ohio, Dr. Cecil Striker, Cincinnati, Dr. John M. Van Dyke, Canton, Ohio, Dr. Robert C. Rothenberg, Cincinnati, chairman of Medical Service Plans, and Dr. J. B. Lukins, Louisville, Ky.

WASHINGTON CONFERENCE

Some fifty physicians representing Pennsylvania, New York, Delaware, the District of Columbia, Maryland, New Jersey and Virginia held a session in connection with the regular meeting of the Council in Washington, D. C., on December 6. Following the session newspaper statements prepared by Dr. John H. Fitzgibbon, Portland, Ore., chairman of the Council, and Dr. Louis H. Bauer, Hempstead, N. Y., member of the Board of Trustees and former chairman of the Council, were released emphasizing the following seven point program:

- 1 Continued expansion of the practice of medicine with full development of approved voluntary hospital, medical, indemnity, industrial and commercial insurance against the costs of medical care.

- 2 Development of public health facilities for preventive medicine all over the country.

- 3 Development of adequate diagnostic facilities wherever possible.

- 4 The use of the voluntary insurance principle in caring for the indigent and medically indigent.

- 5 The development of hospital facilities where present facilities are used to the utmost and are still inadequate.

- 6 The use of federal funds to aid communities in public health measures, care of the indigent and construction of necessary hospitals, when local communities are unable to finance the projects, but with retention of local administration.

- 7 The creation of an agency of the federal government for coordinating and administering medical health functions of the federal government exclusive of the Army and Navy.

The morning session was devoted to explanatory remarks from representatives at A. M. A. Headquarters, among them being Dr. Carl Peterson, Secretary of the Council on Industrial Health, Mr. J. W. Holloway Jr., Director of the Bureau of Legal Medicine and Legislation, and Lieut. Col. H. C. Lueck, Liaison Officer, Procurement and Assignment. In addition to Dr. Fitzgibbon and Dr. Bauer, other Council members who attended the meeting were Dr. Alfred W. Adson, Rochester, Minn., Dr. E. J. McCormick, Toledo, Ohio, Dr. James R. McVay, Kansas City, Mo., Dr. Thomas A. McGoldrick, Brooklyn, Dr. W. S. Leathers, Nashville, Tenn., and Dr. James L. Paullin, Atlanta, Ga.

Prepayment medical insurance plans again were the principal subject of the discussion during the afternoon. Dr. Walter Donaldson, Pittsburgh, presented a statement by the Pennsylvania Medical Society asking that the principles for prepayment medical insurance plans laid down by the American Medical Association specifically endorse service plans as well as cash indemnity or reimbursement plans. Dr. Fitzgibbon stated that it was his understanding that the principles not only included service plans but recommended and encouraged the experimentation and initiation of voluntary prepayment insurance plans by local state and county groups. Louis Reed, United States Public Health Service, gave an analysis on various plans and stated that more and more the plans were merging into combination service indemnity plans.

KANSAS CITY CONFERENCE

Dr. James R. McVay presided at the third meeting held in Kansas City on December 17, which was attended by representatives of the South Central group of states including Arkansas

Colorado, Illinois, Kansas, Missouri, Oklahoma and Texas. It was unfortunate that transportation difficulties and conflicting local state medical societies kept representatives from other states in that section from attending this meeting. It is hoped that states which did not attend the conference will be able to attend one of the series of meetings scheduled on the West Coast in April. Talks by representatives of the American Medical Association included a discussion by Dr. F. H. Arestad, who had not spoken at the other conferences. Dr. Arestad told how the Council on Medical Education and Hospitals is integrating its work with the Bureau of Information, which is giving special consideration to the problems that will face medical officers following their release from service in the armed forces. Dr. R. B. Anderson, Fort Worth, Texas, in speaking as a representative of Texas, reminded the group that the "Shoulders plan," which had been given unanimous endorsement by the House of Delegates of the American Medical Association and the American Legion following World War I, should be again brought into light. He told of the provisions of this program to provide locally for veterans rather than nationally. Dr. Anderson urged reconsideration of this plan as an answer to the problem of caring for veterans. Dr. Barrett A. Nelson, Manhattan, Kan., discussed some of the problems Kansas is facing in drawing up a bill for presentation to the Kansas legislature for enactment. Dr. Ira H. Lockwood, Kansas City, president of Surgical Care, Inc., and for many years a member of the Medical Economics Committee of the Missouri State Medical Association, spoke of the principles of Surgical Care, Inc., and how it is working in Missouri.

An abstract of the Atlanta meeting will appear in an early issue of THE JOURNAL.

Washington Letter

(From a Special Correspondent)

Feb. 26, 1945.

Hill-Burton Hospital Bill Hearings Held

Hearings on the Hill-Burton Hospital Construction bill (S. 191) commenced today under the chairmanship of Senator James E. Murray of Montana, chairman of the Committee on Education and Labor. Following a recommendation made in January by the Pepper Committee on Wartime Health and Education, the bill authorizes a system of federal aid and grants to states or through the states to other public and nonprofit agencies for hospital planning and construction. The sum of \$105,000,000 would be allocated among states for the next fiscal year on the basis of population and financial need. Federal contribution would vary from 25 to 75 per cent. An additional \$5,000,000 would be distributed among the states for surveys and plans. Witnesses heard today were Dr. Donald C. Smelzer, president, American Hospital Association, Philadelphia; Rev. Alphonse M. Schwitalla, S.J., Catholic Hospital Association, St. Louis; Rev. John G. Martin, president, American Protestant Hospital Association, Newark, N. J.; Dr. Ernst P. Boas, New York. Later witnesses to be heard are, for February 27, Dr. Reginald Atwater, executive secretary, American Public Health Association, New York; Dr. George S. Stephenson, National Commission on Mental Hygiene, New York; Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, and Dr. Martha Eliot, Children's Bureau, U. S. Department of Labor, Washington, D. C.; and, for February 28, Dr. R. L. Sensenich, Board of Trustees, American Medical Association, Chicago; Dr. Victor Johnson, Secretary, Council on Medical Education and Hospitals, American Medical Association; Joseph Fichter, master, Ohio State Grange, Columbus, Ohio, and Dr. A. Rand, Washington, D. C.

Medical Members of New Research Board for National Security

The medical profession is well represented on the new Research Board for National Security, which will extend into peacetime the wartime research conducted by the temporary Office of Scientific Research and Development. Dr. Vannavar Bush of the Carnegie Institution of Washington, and now director of OSRD, has declined an invitation to become a

member of the new committee, stating that he did not wish to appear to dominate the new organization. The committee is formulating programs of scientific research and development to strengthen national security. Its appointment results from a report of the Congressional Committee on Postwar Research and Development, headed by Charles E. Wilson. Chairman of the Research Board for National Security is Dr. Karl T. Compton, president, Massachusetts Institute of Technology, and among the four executive committeemen are Dr. A. R. Dochez, professor of experimental medicine and surgery, College of Columbia University Physicians and Surgeons, and Dr. Roger Adams, head of the chemistry department, University of Illinois. Among members of the research committee are Dr. H. S. Gasser, director, Rockefeller Institute for Medical Research; Dr. A. Baird Hastings, professor of biochemistry, Harvard University; Dr. W. S. Hunter, professor of psychology, Brown University, and chief, Applied Psychology Panel, National Defense Research Committee; Dr. Lewis H. Weed, director, Johns Hopkins University School of Medicine, and chairman, Division of Medical Sciences, National Research Council; Major Gen. Norman T. Kirk, Surgeon General of the Army, and Vice Admiral Ross T. McIntire, chief, Bureau of Medicine and Surgery, U. S. Navy.

Expansion of Health Facilities Urged for Postwar Period

Great expansion and development of present health facilities and programs is required to meet the health needs of the 15,000,000 returning veterans of this war, according to an interim report on Health Needs of Veterans, announced today by Senator Claude Pepper's Senate Subcommittee on Wartime Health and Education. Further studies will be made on the quality of medical care being provided for American war veterans with a view to making concrete recommendations. "The men and women in the services," said Senator Pepper, "have become accustomed to the best in medical and hospital care, and they will not be satisfied with anything less than the best when they return to civilian life." Continued investigations will be made with the help of medical authorities, veterans' organizations and professional health groups. The interim report was signed by all five members of the subcommittee: James M. Tunnell, Democrat, Delaware; Elbert D. Thomas, Democrat, Utah; Robert M. LaFollette Jr., Progressive, Wisconsin; H. Alexander Smith, Republican, New Jersey, and Chairman Pepper, Florida.

Physicians of Maryland and of the District of Columbia May Compose Differences.

A joint committee of both houses of the Maryland legislature has asked the Maryland Board of Medical Examiners to reconsider its ban on borderline certificates to allow District doctors to practice across the Maryland state line. Dr. George C. Ruhland, health officer of the District of Columbia, and Theodore Wiprud, secretary of the District of Columbia Medical Society, appeared before the legislative committee. Three months ago the Maryland board rescinded a reciprocity agreement under which certificates had been issued Washington and Maryland doctors for the past sixteen years. Since the \$1 certificates were discontinued, District doctors wishing to attend patients in Maryland have been forced to obtain a \$50 Maryland license and pass the state examination. District officials say a favorable response to their pleas for reissuance of the certificates is expected.

Four Hundred and Fifty UNRRA Teams Requested by General Eisenhower

General Eisenhower, Supreme Allied Commander, has requested that 450 United Nations Relief and Rehabilitation Administration teams consisting of 10 men each be appointed on a stand-by basis, to be ready for the defeat of Germany. Meantime international organization is proceeding, Director General Herbert H. Lehman announcing the appointment of Rolf Nugent as deputy chief of UNRRA's Yugoslav mission.

Official Washington is studying reports from London of criticism of UNRRA for reported failure to get relief work under way on a larger scale. Chief difficulty has been said to be in lack of understanding between UNRRA and the Army.

EXPANSION OF MATERNAL AND CHILD HEALTH AND CRIPPLED CHILDREN'S PROGRAMS

Recommendations Adopted by the Steering Committee on Health Services Advisory to the Children's Bureau, U. S. Department of Labor, Washington, D. C., January 28

There is ample evidence that urgent need exists for a widespread expansion of local, state and federal programs to assure the accessibility of health and medical services to all mothers and children. Though great progress has been made during the nine years the Social Security Act has been in operation, the coverage of the country with health services for mothers and children is far from complete and the facilities and personnel to provide a high quality of service and care are still very inadequate. Though evident reduction has occurred in infant and maternal mortality and in the incidence of certain diseases, workers familiar with the problem know that the improvement has varied greatly in different areas and that generally it has taken place in direct proportion to the amount and kind of service and facilities made available. It is well known that in many parts of the country mortality and morbidity rates are far greater than the "average." The rejection rates for selective service have high-lighted what has long been known, but to some extent disregarded, namely that a large proportion of the nation's children are not reaching maturity as physically and mentally fit as is consistent with the knowledge and potential resources available in this country. That more than one in every four of our 18 year old boys who come up before Selective Service is rejected as physically or mentally unfit for general military service is indeed shocking.

Many children today do not receive preventive and curative care compatible in amount or in quality with the present day standards of good pediatric service; many mothers do not receive the kind of obstetric care that is recognized as the best. The reasons that mothers and children do not receive this service are that (1) such services and facilities are not distributed widely but are concentrated to a great extent in the larger urban centers, (2) many families are unable to pay for service even when it is available in the community and (3) neither the provision of medical care nor the education of parents on how to use facilities has kept pace with scientific knowledge.

It is essential, therefore, that all necessary services—preventive, diagnostic and curative—be made available to all mothers and children as rapidly as possible. It is equally essential that such services be of high quality and that they be designed to meet the needs of mothers and children as individuals.

Though extensive expansion is not possible during the war period because of lack of personnel, this period can be used for planning for the training of key personnel, for exploring ways and means to make fuller use of existing personnel and resources and to extend and improve services and facilities, and for starting demonstrations of different kinds of services that will serve as "pilot" projects for postwar expansion. This would make it possible for the program to go forward as rapidly as personnel and facilities become available.

As a basis for action it is necessary to gather data on personnel and facilities for health service and medical care for mothers and children, state by state, to bring into focus local needs. Such state reviews of resources and needs can serve

both as supporting evidence for national planning and as specific guides to state and local administrative bodies.

To consider ways and means of meeting these needs, the Children's Bureau advisory committees concerned with maternal and child health and crippled children's services met in December 1944 and made full recommendations to the Children's Bureau.

To bring these recommendations together and point them up for specific action, the chairmen of the committees and subcommittees (or their representatives) met as a special Steering Committee on Health Services on January 28 at the Children's Bureau.

The Steering Committee on Health Services urges the Children's Bureau to take the steps necessary to implement these recommendations.

The recommendations are as follows:

1. *Increase in Federal Grants to States for Maternal and Child Health and Crippled Children's Services.*—The Children's Bureau should seek at once through appropriate legislative measures additional federal funds for grants to the states in amounts adequate to carry out the recommendations of the advisory committees on maternal and child health services and on services for crippled children for expansion of the respective programs.

2. *Statewide Coverage.*—Funds for these services should be made available in sufficient amounts to allow progressive expansion of the programs until each state is able to assure the availability of these services to all mothers and children within the state.

The state plans should show the steps that will be taken and the method that will be developed to provide such statewide coverage within a limited period, preferably not more than ten years.

A state plan should provide measures to make known to all communities the availability of health facilities for maternity and child care, including transportation to such facilities when needed.

3. *Expansion of Community Health Services for Mothers and Children.*—Health services, including treatment services, should be made available throughout every state for mothers and infants, and for children of all ages, including those in school and those at work. These health services should include periodic health examinations, provision for medical care when conditions are found that are detrimental to health, growth or development or when children are sick, dental health service and care (including care for the pregnant and nursing mother) and mental health service at all stages of the child's development (and for the mother during the maternity period).

School Health Service: Special emphasis should be placed on the improvement in school health services, including those in academic and vocational high schools. The services of preventive, diagnostic and treatment agencies should be coordinated with programs of health instruction or other services provided by departments of education and welfare. Normal school and in-service education of teachers should include preparation in the recognition of normal growth and development of children, the signs and symptoms of illness, and the conditions governing a healthy and safe school environment.

Special emphasis should be placed on the need for improved diagnostic services among school children and on the organization of facilities for medical care of children with adverse health conditions.

Since rheumatic fever among children of school age is of such great importance, particular attention should be given to the development of appropriate diagnostic services to detect this disease early.

Hospital and Clinic Care for Mothers and Children: Financial provisions should be made without further delay to provide adequate clinic and hospital service to mothers, infants and children as part of the community health service and to assure continuity of care for maternity patients and newborn infants.

The Steering Committee on Health Services is composed of chairmen of standing subcommittees of the Children's Bureau; namely: *Maternal and Child Health Services*, Dr. Nicholson J. Eastman of Johns Hopkins; *Medical Services*, Dr. George M. Whipple of the Mayo Clinic; *Advisory Committee on Crippled Children*, Dr. Oscar L. Miller of the North Carolina Orthopedic Hospital; *Advisory Committee on Rheumatic Fever*, Dr. T. Duckett Jones of the House of Representatives; *Advisory Committee on Medical Social Work*, Dr. George M. Whipple of Cambridge, Mass.; *Advisory Committee on Mental Hygiene*, Dr. George S. Stevenson of the National Committee for Mental Hygiene, Inc.; and the *Committee on Maternal and Child Health* of the Association of State and Territorial Health Officers, Dr. Felix J. Underwood, executive officer of the Mississippi State Board of Health. The meeting on January 28 was attended also by Dr. Joseph S. Wall, president, American Academy of Pediatrics; Dr. George M. Whipple, assistant medical director, Metropolitan Life Insurance Company, New York; and Miss Hazel Corbin, general director, Maternity Center Association, New York, all members of the Children's Bureau Advisory Committee on Maternal and Child Health Services.

Hospital Construction: In the development of plans for hospital construction, special consideration should be given to the need of making adequate provision for maternity beds and for pediatric beds, including those for newborn infants, for children with communicable diseases and for children requiring prolonged sanatorial or convalescent care.

Care of Premature Infants: A greatly expanded program for the care of premature infants, developed as an integral part of the community health program, should be inaugurated to the end that all general, children's and maternity hospitals shall be equipped with modern nurseries under the supervision of qualified pediatricians and pediatric nurses. State health agencies should designate premature birth as a reportable condition of an emergency character, and emergency transportation facilities should be provided when necessary.

Obstetric, Pediatric and Other Consultants: Each state department of health should employ on its staff qualified obstetric and pediatric consultants to supervise health clinic services for mothers and children, to coordinate service in clinics with care in hospitals and so provide for continuity of service, and to serve in an advisory and consultative capacity to local physicians on the care and management of obstetric and pediatric patients. Similarly, consultants in mental health and dental care should be employed for like purposes.

Education in Maternity and Child Care: A continuous nationwide educational program as to what constitutes adequate care during maternity, infancy, early childhood and later childhood (including adolescence) should be carried out. State and local health agencies should develop programs of adult education in health subjects with emphasis on education for parenthood. Education departments should emphasize instruction in maternal and child health in appropriate courses. Suitable printed and other educational materials should be made available to parents at the appropriate time, and the use of similar material in high schools should be incorporated in the curriculum. Special attention should be given to the development of visual aids, such as exhibits, posters and films. It is of utmost importance that the quality of the preventive and treatment services be such as to reinforce and enhance this educational program in maternity and child care.

The Children's Bureau is urged to outline ideal standards for maternity and child care, including care of crippled children, and to publish and distribute these standards widely through national, state and local agencies, official and voluntary. In addition, it is essential that the federal agency should establish minimum requirements on standards of care for services under state programs receiving federal financial aid.

4. Expansion of Service for Crippled Children.—Crippled children's services should be extended through provisions for clinic, hospital and other types of care, as indicated, until complete service is made available to the entire nation.

Rheumatic Fever: In view of the fact that rheumatic fever, together with rheumatic heart disease, is the leading cause of death from disease among children of school age, and in view of the recognized need for the extension of services for children with this disease, a rheumatic fever program should be developed in each state. The program should include diagnostic and treatment services and aftercare and should be expanded as rapidly as the availability of personnel and facilities will allow until the service is statewide.

Children with Cerebral Palsy: Special provisions should be made for children with cerebral palsy, with emphasis on its prevention through competent obstetric care. Encouragement should be given to the establishment of special centers for the training of children with cerebral palsy.

Other Physical Handicaps: Diagnostic and treatment services for crippled children should be extended to include children of all ages with other physically handicapping conditions, such as visual and hearing defects or diabetes or other chronic diseases. Special emphasis should be placed on coordination of these services with the school health services and on utilization of the school health service as a case finding source.

5. Administration of Crippled Children's Program by State Health Departments.—In view of the fact that the crippled children's program is one primarily involving medical care, it is recommended that all crippled children's programs be administered by state health departments.

The Children's Bureau and the responsible state agencies should continue to work for the elimination of court action in determining children's eligibility for care under the crippled children's program.

6. Improvement in the Quality of Care.—A state plan for maternal and child health or crippled children's services should include provision for continuing improvement in the quality of the care given. This implies that full consideration be given to the needs of each patient and that all community resources be mobilized for this purpose. The organization and administration of the services should be sufficiently flexible to meet the range of individual needs.

To assure care of high quality, a state plan should provide for—

(a) Qualification standards for administrative and clinical personnel and institutional services.

(b) Opportunity for graduate and postgraduate training for all personnel necessary to administer the program or provide care.

(c) Sufficient personnel and facilities and adequate remuneration.

(d) Consultant service in obstetrics, pediatrics, orthopedics, mental health, dental health and other specialties as required.

(e) Use of adequately equipped health centers, hospitals, clinics and laboratories.

(f) Use of groups of physicians, individual private practitioners, nurses, social workers, nutritionists and other professional workers for the purpose of effectively coordinating preventive, diagnostic, consultative and curative services.

(g) Effective use of community welfare, education and rehabilitation services.

(h) Suitable distribution of hospitals, convalescent and other facilities, diagnostic and therapeutic services, and transportation of patients to these services when necessary.

(i) A planned relationship between centrally located hospitals with special diagnostic and therapeutic services, local community hospitals, clinics, health centers and practicing physicians.

To assure nationwide care of high quality, the federal agency should—

(a) Develop national standards of care and establish minimum requirements.

(b) Provide grants-in-aid to the states that will make possible equalization of opportunity for care of high quality.

(c) Aid in the training of personnel and in the development of facilities.

7. Provision for Training Personnel.—As far as may be found to be necessary, federal funds should be made available to states to provide well trained personnel for carrying out the services under the maternal and child health and crippled children's programs by granting fellowships, scholarships and special stipends for all types of professional personnel to be employed under these programs.

Funds should also be made available to make possible the development of new courses for the training of professional personnel when such courses are found to be necessary. This may involve responsibility in helping to define curriculum content in new areas of service where it is now undefined. Old courses need to be improved and new courses developed to coordinate and integrate training in the fields of clinical medicine and public health.

8. Expansion of Advisory Services and Investigations by Children's Bureau.—Personnel should be made available by the Children's Bureau to assist the states in the development of coordinated community programs and the integration of health, welfare and educational services for mothers and children within the states and in the development and proper utilization of advisory committees.

The Children's Bureau should develop a unit on school health, which, in cooperation with the Office of Education and the U. S. Public Health Service, will work with the several state health agencies to carry out the recommendations in this report relating to the school health program. The functions of such a school health unit should also include program planning in cooperation with the U. S. Public Health Service and the Office of Education—such planning to involve assistance to the states in the preparation of school health personnel, improvement of case

finding procedures in the schools and diagnostic services, the development and utilization of community treatment facilities for care of adverse health conditions found in school children, and the study of methods of preventing such conditions.

A consulting psychiatric staff should be established within the Children's Bureau to advise states and communities in planning psychiatric and mental hygiene services for children, to advise the Children's Bureau on the training of personnel for this field, and to cooperate with the staff of the U. S. Public Health Service with respect to those aspects of its mental hygiene activities that concern children.

Appropriations to the Children's Bureau should include adequate funds to enable the bureau to administer effectively the programs of grants to states, to undertake investigations, administrative studies and demonstrations on maternal and child health and crippled children's services, to make reports on such studies and to promote postgraduate training and education in these fields. As circumstances permit, increased effort should be devoted to studying and reporting on programs and methods as developed by the various states in order to stimulate exchange of ideas and experience.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Change in Status.—H. R. 2277 has been reported to the House of Representatives, proposing to enact a "Nurses' Selective Service Act of 1945." This bill provides that every female residing in the United States who has reached the twentieth anniversary of her birth but who has not reached the forty-fifth anniversary and (1) who has been a registered nurse in any state, territory or possession of the United States or in the District of Columbia or (2) who is a graduate of a school of nursing and eligible to apply for examination for registration as a registered nurse in the jurisdiction in which such school is situated or in which she resides will be made subject to registration and selection for and induction into the land and naval forces of the United States under the Selective Training and Service Act of 1940, as amended.

Bills Introduced.—S. 581, introduced by Senator Downey, California, proposes to confer benefits of hospitalization and privileges of soldiers' homes on certain persons who served in a civilian capacity under the jurisdiction of the Quartermaster General during the War with Spain, Philippine Insurrection or the China Relief Expedition. H. R. 2180, introduced, by request, by Representative Herter, Massachusetts, proposes to enact a "Merchant Marine Veterans' Readjustment Act of 1945." This bill follows closely the provisions of the G. I. Bill of Rights and, in addition, authorizes the chairman of the United States Maritime Commission and the United States Public Health Service to provide adequate facilities for the medical, surgical and dental treatment and hospitalization without charge for merchant marine veterans and dependent members of their families. H. R. 2234, introduced by Representative Traynor, Delaware, proposes to provide grants to states, political subdivisions of states and municipalities for developing and maintaining dental health plans consisting of effective measures for dental health education and for the prevention, treatment and control of dental diseases. H. R. 2253, introduced by Representative Priest, Tennessee, proposes to establish in the Veterans' Administration a commissioned service consisting of physicians, surgeons, dietitians, nurses and medical technicians.

STATE LEGISLATION

Maryland

Bills Introduced.—S. 306 proposes to enact a separate chiropody practice act and to create a board of chiropody examiners, to be selected by the board of medical examiners, to examine and license applicants for licenses to practice chiropody. H. 310 proposes to enact a separate naturopathic practice act and to create an independent board of naturopathic examiners to examine and license applicants for licenses to practice naturopathy. H. 330 proposes to enact a separate practice act for physical therapy practitioners and to create a board of physical

therapy examiners, to be appointed by the governor from a list submitted by the Medical and Chirurgical Faculty of Maryland, to examine and license applicants for licenses to practice physical therapy. Physical therapy is defined to be "the therapeutic use of physical agents other than drugs, the use of physical, chemical and other properties of heat, light, water, electricity, massage, exercise, medical gymnastics, analysis as taught in physical therapy schools, and radiation, exclusive of x-ray radiation or radium treatment. It shall be the duty of all licensed physical therapists to conduct themselves in an ethical manner and to practice in all ways in conjunction and complete cooperation with the licensed medical practitioners of this state."

Massachusetts

Bills Introduced.—S. 421 proposes to make it unlawful for any hospital supported in whole by the commonwealth or any subdivision thereof to receive medical students in the institution for the purpose of clinical instruction, service and observation unless similar opportunities are made available to students of all legally chartered medical schools in the commonwealth. H. 1150 proposes to prohibit the operation of a convalescent or nursing home without a license from the department of public welfare.

Nebraska

Bill Introduced.—L. B. 355, to amend the laws relating to chiropractic, proposes to authorize chiropractors to sign death certificates.

New Mexico

Bills Introduced.—S. 35 proposes to authorize the establishment and operation of four state general hospitals to provide general medical care and treatment for the people of the state. S. 194 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a physician's certificate, based on examination and laboratory test, that the party is either not infected with syphilis or, if so infected, is not in a stage of that disease which may become communicable to the marital partner. S. 204, to amend the laws relating to the practice of osteopathy, proposes, among other things, to accord osteopaths the same right as physicians of other schools of medicine with respect to the rendering of medical services under the provisions of public health, welfare and assistance laws. The bill proposes specifically to provide that no plan or program which discriminates against osteopaths shall be approved by any public official.

Texas

Bill Introduced.—S. 52, to amend the workmen's compensation act, proposes to afford compensation for disabilities arising from stated occupational diseases contracted in the course of employment.

Official Notes

DOCTORS LOOK AHEAD

Broadcast on the largest network (one hundred and twenty-three stations) ever made available for a nonprofit health education program, Doctors Look Ahead takes up vital problems of our fighting forces and our people at home. The next three programs will deal with the following topics:

March 3. Nutrition at Home. Speaker, Dr. G. K. Anderson, Secretary of the Council on Foods and Nutrition of the American Medical Association.

March 10. Rheumatic Fever.

March 17. Women at War, in cooperation with the Office of War Information, speaker to be announced.

In view of the paper shortage, no invitations are being issued to listeners to write in. Nevertheless the program is attracting a considerable audience mail, indicating a widespread public interest in the vital topics which are being discussed. The dramatic qualities of the broadcasts are receiving complimentary attention in radio circles.

This program, which began January 6, will continue through June 30 each Saturday at 4 p. m. Eastern War Time (3 p. m. Central War Time, 2 p. m. Mountain War Time and 1 p. m. Pacific War Time).

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ALABAMA

Public Health . . . Is Many Things.—The state department of health has recently published a thirty-six page booklet entitled "Public Health . . . Is Many Things" Brought out under the direction of Dr. Burton F. Austin, Montgomery, state health officer, the booklet is aimed to disseminate information concerning the activities of the state department of health. Included among the discussions are Keeping Water Supplies Safe; The Public Health Nurse Plays an Important Role; Cancer-Control Program is Aimed at an Ancient Enemy; Free Maternity Care for Mrs. G. I. Joe, Building a Stronger State with Better Food; Rabies Research in Alabama; Public Health Makes Gains in War on Venereal Diseases, Malaria, the Plague of the Centuries, is Being Mastered; Medical Science Pulls Fangs of Deadly Tubercle Bacillus; Rat Destruction Holds Key to Endemic Typhus Control, Motion Picture is Enlisted in the Fight on Disease and Negroes Greatly Complicate State's Health Problems. Other discussions answer average questions in the lay person's mind concerning the bureau of vital statistics, show the state board's activities in releasing health educational material through lectures and other sources, demonstrate the service of the library in obtaining health information and discuss service and efforts carried out in protecting food, drink, and communicable and industrial diseases. The well illustrated booklet depicting the activities of the department is concluded with an analysis of the per capita cost of public health and combined range of figures showing the state's health for certain periods.

CALIFORNIA

Service Officers May Treat Civilians in National Parks.—The San Francisco *News* recently reported that Attorney General Robert W. Kenny ruled that service medical officers not licensed in California may treat civilian visitors in national parks if a civilian doctor is not employed. The opinion was sought by the state board of medical examiners, which questioned whether a navy doctor stationed at Yosemite National Park for the benefit of servicemen that were quartered there could serve civilians.

Personal.—Dr. Jacob C. Geiger, director of public health of the city and county of San Francisco, recently received the official medal of the National Order of Merit, "Carlos Manuel de Cespedes." The medal was awarded by Dr. Ramon Grau San Martin, president of Cuba, also a physician.—Dr. Orvall Smiley, resident physician for the Pacific Coast and Electric Company at Big Bend, has been appointed to a similar position with the Folsom State Prison, filling a position that has been vacant for a number of years. Dr. Smiley is taking over work now being done on a part time basis by two private practitioners, Drs. Paul DeWitt Barnes, Loomis, and James F. McAnally, Roseville.—Dr. Alfred C. Dick, medical director of the Consolidated Vultee Aircraft, box 685, La Jolla, has resigned.—Dr. Edith F. Young, San Francisco, is the new health officer of Sonoma County.

CONNECTICUT

Charles Bartlett Celebrates Eightieth Birthday.—Dr. Charles J. Bartlett, emeritus professor of pathology, Yale University School of Medicine, New Haven, and for many years president of the Connecticut Medical Examining Board, recently was guest of honor at a dinner at the New Haven Medical Association given in recognition of his eightieth birthday. Dr. David R. Lyman, Wallingford, was toastmaster at the dinner and speakers included Drs. H. Gildersleeve Jarvis, Hartford, president of the state medical society, Thomas P. Murdock, Meriden, of the state medical examining board, Joseph I. Linde, health officer for the city of New Haven, and Marvin M. Scarbrough, president of the New Haven Medical Association.

Health and Human Relations.—Dr. Charles J. Prohaska, Hartford, state supervisor of health and physical education, is the coordinator of a lecture and work-shop course in health and human relations which opened at the New Haven State

Teachers College, February 8. The first session was devoted to orientation and the second to a lecture by James H. S. Bossard, Ph.D., University of Pennsylvania, Philadelphia, on "Family Background for Social Hygiene." Among others participating in the series are:

Rev. Liston Pope, Ph.D., Divinity School, Yale University, Moral Perspectives on Health and Sex, March 8.
Maurice A. Bigelow, Ph.D., American Social Hygiene Association, New York, Status of Sex Education in the Schools, March 15.
Dr. James S. Plant, Newark, N. J., Growth and Development of the Child, March 22.
Dr. Marion B. Leonard, New Haven, Anatomy and Physiology of Sex, March 29.
Drs. Maurice J. Strauss, New Haven, and Henry P. Talbot, Hartford, Venereal Diseases, April 5.
Charles Edward A. Winslow, Dr. P.H., and Grace Mooney, Ph.D., New Haven, General Aspects of Public Health in Relation to Family Life, April 12.
Frances Roth, Connecticut State War Council, Program of Social Protection in Connecticut, April 19.
Dr. Howard M. Haggard, New Haven, Alcoholism and Its Effect on Family Life, April 26.
Robert Tabet, Philadelphia public schools, Role of the School Counselor in Health and Human Relations, May 3.
Dr. James M. Cunningham, Hartford, Family and Mental Health, May 10.
Harvey J. Fuller, Wethersfield High School and Marjorie Woodlock, Connecticut War Council, Youth Panel, May 17.
Jois J. King, New Haven Teachers College, Approach to Health and Human Relations in Elementary School, May 24.
Jester A. Kirkendall, Ph.D., U. S. Office of Education, Washington, D. C., Teacher Training in Health and Human Relations, May 31.

ILLINOIS

Chicago

Dr. Kretschmer to Address Service for Chronically Ill.—Dr. Herman L. Kretschmer, President of the American Medical Association, will address the Central Service for the Chronically Ill of the Institute of Medicine of Chicago at the Standard Club, March 6. His subject will be "The Problem of the Chronically Ill Patient." Dr. William F. Petersen, chairman of the administrative committee, will preside at the meeting.

Personal.—At the recent annual meeting of the board of governors of the Institute of Medicine of Chicago, a resolution was unanimously adopted commending James C. Leary, science editor of the Chicago *Daily News*, for his valuable reporting of medical affairs, especially for much needed publicity concerning local health conditions and problems, and of grateful appreciation for his interest and cooperation in the activities of the Institute of Medicine of Chicago. Mr. Leary is now preparing to go to the European theater of operations as war correspondent for the *Daily News*.

Refugee Physician Permitted to Take Examination.—In a ruling February 13 the appellate court upheld the plea of Dr. Leopold Schutz, a German refugee, to be permitted to take an examination for a license to practice medicine. Specifically, the appellate court affirmed the ruling of Judge John C. Leve, who issued a writ of mandamus directing the state department of registration and education to permit Dr. Schutz to take the examination. According to the Chicago *Sun* Dr. Schutz, who was born in Germany, stated that he attended four universities, was graduated from the University of Munich in 1913 and was licensed in 1917. In 1938, he said, the Nazis deprived him of his license and confiscated the transcript record of his studies because he is a non-Aryan. In the case of Dr. Schutz the appellate court ruling was unnecessary, it was stated, because after the ruling by Judge Leve Dr. Schutz had been permitted to take the examination and passed it.

INDIANA

Leroy Edwards Named Professor of Pharmacology.—Leroy D. Edwards, Ph.D., professor of pharmacology, University of Florida, Gainesville, has been appointed professor of pharmacology at the School of Pharmacy at Purdue University, Lafayette, following the vacancy that was created in October 1944 when Curtis H. Waldon, Ph.D., went to the Montana State University, Missoula, to become dean of the School of Pharmacy there.

Tom Hendricks Joins American Medical Association.—Mr. Thomas A. Hendricks, since 1924 executive secretary and head of the bureau of publicity of the Indiana State Medical Association, Indianapolis, has joined the staff of the American Medical Association on a part time basis as Secretary of the Council on Medical Service and Public Relations, with headquarters in Chicago. Mr. Hendricks, who served overseas for thirteen months during the first world war, has been managing editor of the state medical journal for the past ten years.

Writing Among Students.—Twenty-six students in the Indiana University School of Medicine, Indianapolis, achieved distinction during 1944 in writing medical articles, according to an announcement from the school. Included among the students accredited this recognition for work in writing, which Dr. Willis D. Gatch, dean of the medical school, has declared to be an essential part of the training of physicians, are:

Junior surgery papers.—Melvin A. Block, Evansville; Justin E. Arata, Mishawaka; Geraldine M. Zix, Indianapolis; Morris Green, Indianapolis; Donald L. Trinosky, Indianapolis; Charles G. Smith, Indianapolis; Frederick C. Green, Fort Wayne; Willard A. Scanland, Richmond; Paul M. Dassel, Evansville, and William R. Noe, Indianapolis.

Sophomore bacteriology papers.—Robert C. Bartlett, Bloomington; William C. Robertson, Indianapolis; Paul S. Jarrett, Sharpville, and William J. Miller, Fort Wayne.

Sophomore history of medicine papers.—Joseph V. Schetgen, New Castle; William G. Bannon, Kokomo; Robert W. Harger, Indianapolis; Floyd B. Coleman, Martinsville, and John Martin Miller, Indianapolis.

Senior medicine papers.—Ben Wilson Jr., Bloomington; Rex L. Huff, South Bend; Carolyn Mann Rawlins, Hammond; Harold R. Tharp, Trafalgar; Norris J. Kroy, Paragon; Robert F. Lloyd, Fort Wayne, and George S. Westfall, Goshen.

Students writing the junior and sophomore papers have received the annual Osterman awards on the basis of selections made by the editorial board of the *Quarterly Bulletin* of the school of medicine.

KANSAS

State Meeting Canceled.—The Kansas Medical Society announces the cancellation of its 1945 meeting, which was scheduled to be held in Wichita, May 16-17.

New Department of Physical Medicine.—Dr. Gordon M. Martin, formerly of Rochester, Minn., is director of a recently organized department of physical medicine at the University of Kansas School of Medicine, Kansas City, with the title associate professor. The department holds the same status in the medical school as other departments such as surgery and physiology and offers courses in occupational therapy and physical therapy in addition to regular courses being offered to medical students and nurses. A short lecture course in physical medicine is being offered to senior medical students.

LOUISIANA

Symposium on Tuberculosis.—A symposium on tuberculosis scheduled to be held at the Louisiana State University School of Medicine, New Orleans, April 17-19, has been canceled. It was sponsored by the university, the National Tuberculosis Association, the tuberculosis control division of the U. S. Public Health Service and the Louisiana State Tuberculosis Association.

MASSACHUSETTS

Approving Authority Upheld on Accreditation of Middlesex Graduates.—The superior court of Suffolk County on January 5 upheld the Massachusetts Approving Authority for colleges and medical schools that graduates of Middlesex University could not qualify to take state board examinations to practice medicine. Superior Judge Charles C. Cabot is reported to have said, according to the *Connecticut State Medical Journal*, "My decision is primarily based on a comparison of this school with other medical schools concerning which evidence was produced. These were primarily the medical schools of Boston University, Harvard and Tufts College." He is also reported to have said that Middlesex School did not have "adequate financial backing," that the "quantity of its faculty is not sufficient" and that "the most serious deficiency of all is its almost complete lack of clinical facilities for teaching." The law establishing the Approving Authority was signed by the governor of Massachusetts, James M. Curley, in 1936. An editorial in the *New England Journal of Medicine* reports that a photograph taken at the time he signed the bill shows several members of the Massachusetts Medical Society watching the proceedings, including Dr. Charles E. Mongan, Somerville, then president of the society, and Dr. Stephen Rushmore, Boston, then secretary of the state board of registration in medicine, who automatically became a member of the Approving Authority and who is currently dean of the Middlesex University School of Medicine, Waltham. Soon after its establishment the Approving Authority drew up the seventeen qualifications that a medical school must meet in order to be approved.

MICHIGAN

Beaumont Lecture.—Dr. J. Arnold Bergen, associate professor of medicine, University of Minnesota Graduate School, Minneapolis-Rochester, Minn., gave the twenty-fourth annual Beaumont Lecture of the Wayne County Medical Society at the Detroit Institute of Arts, February 19. His subject was "Modern Concepts of Intestinal Infection."

NEBRASKA

Oil Portrait of Dr. Poynter.—On February 14 an oil portrait of Dr. Charles W. M. Poynter, dean of the University of Nebraska College of Medicine, Omaha, was presented to the university by the C. W. M. Poynter Foundation. On this occasion announcement was made of the Poynter Fellowship in the medical sciences, also sponsored by the foundation. The stipend of the recipient of this fellowship is \$1,200 for a period of tenure of ten months, during which time he will be expected to devote his entire time to research under direction of any of the preclinical or preclinical and clinical departments of the college. Applicants should have concluded at least the first two years of medicine and have demonstrated exceptional ability and, in the opinion of the fellowship committee, indicate aptitude for advanced study and investigative work in the medical sciences. The recipient may become a candidate for an advanced degree in the medical sciences under the current rules of the graduate college. Applications for the next academic year are invited. They should be sent to Dr. A. Ross McIntyre, chairman of the fellowship committee, or the secretary of the foundation, John S. Latta, Ph.D. The program accompanying the presentation of the portrait included an address by Col. Edgar V. Allen, M. C., on "The C. W. M. Poynter Foundation." The portrait was presented by Dr. McIntyre and accepted by Chauncey Samuel Boucher, LL.D., Lincoln, chancellor of the university. It was executed by Mr. Edgar Miller, Chicago. The Poynter Foundation was established to honor Dr. Poynter, dean of the medical school since 1929 (*THE JOURNAL*, Sept. 30, 1944, p. 309).

NEW YORK

Wayland Chester Dies.—Wayland Morgan Chester, Sc.D., professor emeritus of biology, Colgate University, died at Hamilton, February 7, aged 74.

Gift to Cornell for Nutrition Building.—Newspapers announced that directors of the Cooperative Grange League Federation Exchange have given \$200,000 to Cornell University, Ithaca, toward providing a suitable building for the Cornell School of Nutrition, established in 1941. Leonard A. Maynard, Ph.D., is director of the school.

Albert Kaiser Named Health Officer of Rochester.—Dr. Albert D. Kaiser, associate professor of pediatrics, University of Rochester School of Medicine and Dentistry, Rochester, has been appointed health officer of Rochester, succeeding Dr. Arthur M. Johnson, who had reached the retirement age late in 1944 but who was retained in the city service by request. Dr. Johnson has served as health officer since 1937; he will retire March 31. Dr. Kaiser graduated at Harvard Medical School, Boston, in 1913.

New York City

Publication Anniversary of Gessner's Bibliography.—An exhibition of books on medical bibliography through the eighteenth century, arranged in honor of the four hundredth anniversary of the publication of Konrad Gessner's bibliography, is on display in the library of the New York Academy of Medicine through April 1.

Francis Carter Wood Honored.—The unveiling of a portrait of Dr. Francis Carter Wood, director of pathologic laboratories and of radiotherapy, St. Luke's Hospital, was a feature of a tea given February 14 at the hospital in recognition of Dr. Wood's completion of fifty years' continuous service as a member of the hospital staff. The portrait was painted by Leonihel Jacobs and was unveiled by Lincoln Cromwell, president of the hospital, where it will be hung permanently. Dr. Wood served his internship at St. Luke's Hospital. He became director of the pathologic laboratories in 1910 and director of radiotherapy in 1921. He is professor emeritus at the Institute of Cancer Research, Columbia University.

OHIO

Creation of Tuberculosis Division.—The Ohio Public Health Council recently approved the establishment of a division of tuberculosis in the state department of health. The project was recommended by the advisory committee on coordination of tuberculosis programs after a two year study. Another recommendation, now in the process of completion, was the conversion of the Ohio State Sanatorium for Incipient Pulmonary Tuberculosis into a hospital for institutionalized mental patients with tuberculosis. The state department has money, plans and specifications for this project but is awaiting the removal of wartime restrictions. Recommendations in the report of the two year study were:

the establishment of two new state institutions for the tuberculous and covered state subsidy to local tuberculosis institutions, both of which were embodied in bills introduced in the legislature in January, and urged the creation of diagnostic treatment centers in the state. Another recommendation asked that x-ray equipment be provided for each of the state institutions and that routine chest examinations be made of all employees and patients in such institutions.

OREGON

Frederick D. Stricker Resigns as State Health Officer.—Dr. Frederick D. Stricker has resigned as health officer of Oregon, according to the *Portland Oregonian*. He has been succeeded by Dr. Harold M. Erickson, assistant state health officer. It was stated that the resignation came almost exactly on the twenty-fifth anniversary of Dr. Stricker's original appointment to the position.

PENNSYLVANIA

Veterans Loan Fund.—The Medical Society of the State of Pennsylvania is planning to create a Veterans Loan Fund to meet the costs of books, equipment, change of location or a short graduate course for returning members of the society from military service. The fund will be built up by pledges of county medical societies through their individual membership. The money will be deposited as a central fund by the Medical Society of the State of Pennsylvania. Ninety per cent of the total amount donated by each county medical society will be used only for loans to returning members of such county society on formal application and approval made through and by such county society. After the fund has completed its usefulness, or at the end of three years after the war is ended, whichever shall be the earlier date, the total balance of the 90 per cent and the names of all outstanding debtors with the amounts involved will be returned to the county society to be disposed of in any way it may designate. Ten per cent of the total amount given by each county society will be maintained by the state medical society as a central fund from which deserving members from counties too small to raise an appreciable fund will be helped on application approved by their respective county society. This fund will be kept for an indefinite period to meet catastrophic needs of veterans or their families. The officer who will administer this fund shall be named by the board of trustees of the state medical society. Pledges to the fund were sent by the state society to county societies under date of February 19. The appeal is made to 7,250 "home front" members and concerns the approximate total of 2,600 fellow members now in military service.

Philadelphia

Merit Award to Colonel Ravdin.—Col. Isidor S. Ravdin, M. C., Harrison professor of surgery, University of Pennsylvania School of Medicine, was recently presented with the award of merit of the Alumni Society of the University of Pennsylvania. *Science* reports that Colonel Ravdin holds the Legion of Merit for outstanding service as commander of an army hospital in India which was organized by the university.

Memorial Gift.—The Temple University Hospital has received \$11,943.44 from the estate of John Edwin Wells, deceased. According to the *Pennsylvania Medical Journal* this money was bequeathed in memory of his wife's father, Dr. Edmund Wales Holmes, who was first surgeon to the Temple University Hospital and served from 1893 to 1903. He was also the first professor of surgery in the Temple University School of Medicine.

WISCONSIN

Alumni Research Foundation Denies Accusations of Illegality.—On February 14 the Wisconsin Alumni Research Foundation filed in the U. S. District Court a reply denying all accusations of illegality and asserting that all actions were designed to safeguard the public interest and preserve legitimate royalty income, newspapers report. The filed reply is an answer to a government suit charging monopoly, price fixing and other violations in connection with the marketing of patented vitamin D products, it was stated. Litigation started about eighteen months ago, when the foundation sued Douglas Laboratories, manufacturing chemists, for patent infringement. The government intervened with a counterclaim against the foundation and last October amended the counterclaim to include seventeen other defendants, naming one individual and ten drug and food companies. Newspapers stated that the case had been scheduled for trial before Judge John Peter Barnes, Chicago, on September 11.

GENERAL

National Negro Health Week.—"A Healthy Family in a Healthy Home" will be the theme of National Negro Health Week, to be observed throughout the country April 1-8. Literature concerning the educational observance may be obtained from the National Negro Health Week Committee, U. S. Public Health Service, Washington 14, D. C.

Meetings Canceled.—The Society of American Bacteriologists announces that its annual session, which was to have been held in Detroit, May 22-25, has been canceled. Leland W. Parr, Ph.D., 1335 H Street N.W., Washington 5, D. C., is secretary-treasurer.—All 1945 meetings of the American Pharmaceutical Manufacturers' Association have been canceled, according to an announcement January 18.—The American Psychiatric Association announces that its annual meeting, scheduled to be held in May in Chicago, has been canceled. There was a meeting of the councilors of the association February 26-27 to consider means of taking care of urgent business of the association arising out of the cancellation of the annual session.

Roy Hoskins Named Salmon Lecturer for 1945.—Dr. Roy Graham Hoskins, research associate in physiology, Harvard Medical School, and director of research of the Memorial Foundation for Neuro-Endocrine Research, Boston, has been selected as the Salmon Memorial Lecturer for 1945, according to the Salmon Committee on Psychiatry and Mental Hygiene, 200 Retreat Avenue, Hartford 2, Conn. "The Biology of Schizophrenia" will be the theme of the Salmon Lecture series to be given at the New York Academy of Medicine, 2 East 103d Street, New York, on three successive Friday evenings, November 2, 9 and 16 at 8:30 p. m. The title of Dr. Hoskins' first lecture will be "Nature of Schizophrenia," the second "Manifestations of Schizophrenia" and the third "Treatment of Schizophrenia and Needs for the Future."

Dr. Spain Retires as Secretary of Allergy Group.—Dr. William Cook Spain, New York, has resigned as secretary of the American Academy of Allergy and has been succeeded by Dr. Karl D. Figley, Toledo, Ohio. Dr. Spain served as secretary of the Association for the Study of Asthma and Allied Conditions for some twenty years, becoming secretary to the American Academy of Allergy, formed by a merger in 1943. In this year Dr. Spain announced that the money which had been allotted to him as secretary of the Association for the Study of Asthma and Allied Conditions, a parent body of the new group, had been assembled into a fund to form an annual Secretary's Prize. The first recipient of this prize was recently announced as Dr. J. Harvey Black, Dallas, Texas, who was chosen for his paper entitled "The Treatment of Urticaria with Synthetic Vitamin K," read at the first meeting of the American Academy of Allergy in New York, Dec. 11, 1944.

Putting the Disabled Veteran Back to Work.—The Industrial Hygiene Foundation of America, Pittsburgh, brought out in January bulletin 3 in a special series entitled "Putting the Disabled Veteran Back to Work." It is published as part II of a panel started at its annual meeting in 1943 and part I of the proceedings of the 1944 annual session. During the year following the 1943 session members of a panel have answered inquiries from industry on procedures for successful job placement of veterans, have examined proposed company plans for reemployment of ex-servicemen and have otherwise provided information and assistance to member companies and industry generally. Members of the panel are:

Dr. Clarence D. Selby, Detroit, medical consultant, General Motors Corporation, chairman.

Col. John N. Andrews, officer in charge of postwar activities, National Selective Service System.

Dr. Harley L. Krieger, Dearborn, Mich., medical director, Ford Motor Company.

A. A. Hendrix, Linden, N. J., personnel director, Eastern Aircraft Division, General Motors Corporation.

I. Dent Jenkins, personnel manager, Harrison Radiator Division, General Motors Corporation.

Dr. Benjamin F. Streets, Sutersville, Pa., medical department, Westinghouse Electric and Manufacturing Company.

Annual Report of Infantile Paralysis Foundation.—A total of \$1,828,859 was authorized by the National Foundation for Infantile Paralysis to be expended in grants and appropriations between Sept. 30, 1943 and May 31, 1944 for research, education and the training of physical therapists, according to a report released February 23. The report covers only an eight month period because of a change in the fiscal year, and future annual reports will cover operations from June 1 to May 31. The report contains the information that a special fund of two million dollars for epidemic aid and other emergencies, has been established by the trustees, as of May 31, 1944, and that last summer's epidemic, the second worst outbreak of poliomyelitis in the history of the United States,

Special Society Elections.—Newly elected officers of the Sociedad Cubana de Dermatología y Sifilografía include Drs. Manuel Alonso Pérez, president; Fernando Trespalacios Gómez, vice president, and Guillermo González Peris, secretary.—New officers of the Sociedad de Estudios Clínicos de la Habana include Drs. Julio F. Schutte Visiedo, president; José Lanza Camps, vice president; Francisco Canosa Lorenzo, secretary; Luis Rodríguez Baz Alfonso, vice secretary; Luis Ortiz Verdes, treasurer, and Alvaro Silva Lopez del Rincón, vice treasurer.

Government Grants to Medical Schools to Depend on the Admission of Women and the Reform of Medical Education

In the House of Commons Mr Willink, minister of health, stated that the Interdepartmental Committee on Medical Schools has recommended a comprehensive program for the reform and development of medical education and research. Recognizing the fundamental importance of these to the future of the country's health services, the government has accepted the principle of increased grants to be distributed by the University Grants Committee to medical schools, postgraduate schools and institutes and hospitals used for teaching and research. The government shares the views expressed in the report on the importance of affording to women opportunities equal to those enjoyed by men for medical training and for obtaining postgraduate experience. It has therefore adopted the recommendation of the committee that future payments of grants to medical schools should be conditional on the school admitting a reasonable proportion of students of both sexes. But it recognizes that schools at present open to only one sex may require periods of varying lengths to adjust their arrangements to a coeducational basis. It proposes that the University Grants Committee in consultation with the university authorities concerned shall be charged with the responsibility of determining from time to time whether the action taken by a school is reasonable. The government attaches equal importance to the revision of the medical curriculum, and increased grants depend on the early completion of this process.

The Centenary of the Birth of the Father of Tropical Medicine

The centenary of the birth of Sir Patrick Manson, "the father of tropical medicine," was celebrated by the Royal Society of Tropical Medicine. Manson's famous diary, in which he recorded his main discoveries from 1873 on, was displayed. Portraits of him at various stages of his career and his drawings of the development of the filarias in the mosquito were shown. Sir Philip Manson-Bahr, his son-in-law, gave an interesting account of his career. In 1866 he went to Formosa, where he was port medical officer for four years and learned the language of the head hunters of the interior. After spending some years at Amoy, a treaty port on the mainland, he returned to Scotland in 1875. Stirred by Lewis's work on filarias in Calcutta he began to work with the microscope and discovered their nocturnal periodicity. In 1878 he demonstrated the life history of the filarias in the mosquito. Then his study of parasites progressed rapidly. He found *Paragonimus westernmanni* in the sputum of a Chinese mandarin and discovered the part played by *Melania libertina*. In 1883 he was appointed dean of the Hong Kong Medical School. Among his first pupils was Dr Sun-Yat-Sen the revolutionary whose life Manson and Cantlie saved when he was kidnaped in London by the Chinese embassy. In 1891 he formed the nucleus of what became the London School of Tropical Medicine. In 1894, arguing by analogy from what he had observed in filarias, he formulated his mosquito malaria theory, which Ronald Ross, then a major in the Indian medical service, proved. In an experiment designed to convince the British government, Manson infected his eldest son then a medical student with benign tertian malaria through the medium of anophelid mosquitoes.

Additions to the British Pharmacopoeia

The last edition of the British Pharmacopoeia was published in 1932, and six addenda have followed. A seventh addendum is to be published in February. In addition to amendments to existing monographs, there will be new ones on amethocaine hydrochloride, amphetamine and its sulfate, aqueous ointments of ammoniated mercury and zinc oxide, cycloprane, dextrose hydrate, injection of protamine insulin with zinc, estradiol monobenzoate, estrone, phenobarbitone soluble, potassium sulfate, progesterone soluble, solution of sodium acetate (anticoagulant or with dextrose), sulfacetamide (and soluble), sulfadiazine (and soluble), sulfaguanidine, sulfapyridine (and soluble), sulfathiazole (and soluble), theophylline with ethylenediamine and thio-pentone soluble. There will also be a general monograph on the production of tablets, with standards of weight and a disintegration test.

Remarkable Results of Forward Surgery in the Invasion of France

The *Army Medical Department Bulletin* states that it is an attractive proposition to bring the military surgeon forward to the patient so as to give early treatment but it is not nearly so simple to accomplish. Much foresight and organization are necessary. Two or more surgical units must be grouped and linked with transfusion units, and there must be good arrangements for nursing and postoperative care. The success of the arrangements in the British army can now be judged from the figures of twenty-one army group records for June to August 1944 during the invasion of France, they refer only to results in forward surgical units. The recovery rate in 1,592 penetrating abdominal wounds was 68 per cent, in 197 nonpenetrating abdominal wounds 90 per cent, in 127 acute conditions of the abdomen 98 per cent, in 292 thoraco-abdominal wounds 46 per cent, in 686 penetrating or perforating chest wounds 85 per cent, in 198 amputations of the arm 95 per cent, in 474 amputations of the leg 86 per cent, in 644 compound fractures of the femur 94 per cent, in 240 penetrating wounds of the knee joint 98 per cent, in 122 severe burns 89 per cent, in 122 cases of gas gangrene 72 per cent, in 297 penetrating headwounds 79 per cent, in 50 fractures of the spine and cord injuries 74 per cent and in 887 maxillofacial wounds 97 per cent.

These figures represent the immediate death rate up to the time when evacuation was considered possible. It is not yet known how many deaths occurred later, but in one series of 50,000 casualties treated at base hospitals the mortality was only 0.4 per cent. The term "nonpenetrating abdominal wounds" covers cases of laparotomy without discovery of an intraperitoneal lesion, although there might be extraperitoneal damage with or without free fluid or blood in the peritoneal cavity, it does not include wounds involving only the abdominal wall. These impressive results are the outcome of devoted, skilful and enthusiastic work.

Diet in Britain and in America Contrasted

The second report on food consumption levels in Britain, the United States and Canada has been prepared by the government. It shows that, in spite of the expansion of military needs and large shipments to the allies, United States and Canadian supplies have been maintained or increased in 1944 as compared with 1943 because of increased production. Food supplies for civilians in Britain showed some improvement on 1943 but continued below the prewar levels for many foods and below the levels in the United States and Canada for dairy products, meat, eggs, sugar and fruit. In both the United States and Canada meat consumption in 1944 was nearly 50 pounds per head more than in Britain. But to compensate for the shortage of these foods the consumption of potatoes and flour was increased and the British now eat substantially more of these

foods than are eaten in the United States and Canada. The minister of food, Colonel Llewellyn, stated at a conference that the inquiry had been most valuable. The main conclusions were that in all three countries food supplies had been maintained and, in some respects, increased compared with 1943.

PALESTINE

(From a Regular Correspondent)

JERUSALEM, Jan. 15, 1945.

Conference of Otorhinolaryngologists

The third conference of Jewish Otorhinolaryngologists in Palestine took place in Jerusalem in September 1944. The agenda contained discussions on allergy of the respiratory tract and its therapy. A specially interesting contribution was the paper read by G. Wittenberg of Hebrew University dealing with the cause of "halzoun." He said that halzoun is the name given in the Near East to a specific laryngopharyngitis caused by worms. Two kinds of worms have hitherto been considered as producing this condition: (1) leeches of the species *Limnatis nilotica*, which reach the mouth on drinking of contaminated water, and (2) young specimens of a trematode, *Fasciola hepatica*. The latter is a common parasite of the liver in cattle and has a complicated life history in which a water snail is involved as an intermediate host. Infection normally occurs through swallowing microscopic encysted cercariae (metacercariae), which develop in the snail and abound in the water of pools and lakes in which the snails live. The Lebanese investigator Khuri propounded the view that in man in the course of eating insufficiently cooked infected lamb liver the parasite is released and attaches itself to the mouth or adjacent cavities. Khuri attributed to this parasite various disorders and sometimes even death by asphyxiation. Khuri's explanation appears to be doubtful, since it contradicts the normal course of the life history of *Fasciola hepatica*. An additional explanation is suggested by a case of Drs. Marshak and Gorshiev in Tiberias, who extracted an unknown worm from the throat of a patient. This worm proved to be the trematode *Clinostomum complanatum*, a common parasite of fish-eating birds. The birds infect themselves by eating fish which contains encapsulated larvae of the parasite. The case reported is the second on record in man, the other one having been described in Japan. It is suggested that many cases of undetermined "halzoun" might well have been produced in this way by *Clinostomum*.

Diseases Among Immigrants

Jewish Palestine is confronted with a new medical problem consisting in the treatment and medical supervision of new immigrants. J. Meyer opened the discussion on the subject by viewing the fate of the future settlers from a preventive-medical point of view. While in prewar time a selection of the immigrants was possible, Palestine Jewry is now moved only by the wish to save as many people as possible from European countries, thus imposing on the medical profession of this country the task of coping with a number of new medical problems. The "Children from Yemen," for example, presented a high percentage of trachoma, while the group of "Teheran Children" was especially characterized by their great number of skin diseases. Among 2,150 young immigrants who arrived recently 30 had tuberculosis in comparison to 5 cases among 8,000 earlier young immigrants. Increase of the number of hospital beds and a center for preventive medicine were pointed out as an urgent need. The last mentioned problem was particularly stressed by Gruschka. An organized medical service should preeminently be concerned with early diagnosis and timely institution of therapy, the supervision of particularly exposed groups and the after-treatment of diseases. From a scientific point of view as well as with the object of better cooperation of all participating factors, the hospital should have a central and governing position within this framework of a medical service.

SWITZERLAND

(From Our Regular Correspondent)

GENEVA, Jan. 26, 1945.

Swiss Doctors Do Not Want to Become Civil Servants

In a meeting recently held in Berne, representatives of the Medical Association of each "canton" and of the Central Committee of the Swiss Medical Federation discussed propositions coming from certain circles with a view to organizing the medical profession on a civil service basis. A resolution, unanimously adopted by the meeting, expressed the willingness of all doctors to collaborate loyally in the establishment of a true social insurance system. But the delegates remained persuaded that the suppression of an independent medical body, replaced by medical civil servants with a fixed salary, would mean a leveling of all medical activities and would not prove to be of interest for the patient in the long run. All Swiss doctors are therefore strongly opposed to any attempt to make the medical profession a state organization.

Swiss Medical Aid to Ex-Occupied Countries

Two public health missions have gone to give medical help to Marshal Tito's soldiers in Yugoslavia. They are led by Dr. G. Piderman and by Professor Moser of Zurich and have taken with them medical supplies to the value of 75,000 Swiss francs, surgical apparatus and insecticides. The first reports say that there are absolutely no sanitary facilities in ex-occupied parts of Yugoslavia and that the food situation is frightful. A similar but larger mission is about to start for France with Dr. Henri Tecoz of Lausanne at its head. Dr. Tecoz, who is a fellow of the Royal Society of Medicine, worked in France during the first world war, when he was honored with the Legion of Honor and the Epidemics Medal.

The DDT Substances, a Great Swiss Discovery

Resuming studies began in 1874 by O. Zeidler, three Swiss chemists, Drs. Luger, Martin and Muller, have been able to obtain by synthesis dichlor-diphenyl-trichlormethyl-methane (DDT), a remarkable insecticide which has now been utilized by Allied forces and people of ex-occupied territories in fighting malaria; exanthematic typhus and every insect pest.

A Swiss Tropical Institute

Recently created in Basel, the Tropical Institute has now taken possession of its premises in a fully equipped building. The institute aims at pursuing all scientific studies pertaining to the tropics and at giving practical and special training to Swiss or foreign people who want to go to the colonies.

Penicillin in Switzerland

A small quantity of penicillin has just arrived in Switzerland, where it has been distributed among the ten biggest university clinics. Experiments are in process to study the therapeutic activity of the substance in all infectious diseases.

Marriages

GEORGE WASHINGTON FREEMAN SINGLETON to Miss Minnie Elizabeth Johnson, both of Selma, Ala., November 16.

CHARLES OLIVER HUMPHRIES, Asheville, N. C., to Miss Josephine Henderson of Chapel Hill, December 30.

ROBERT MILTON YOUNGLOVE, Bass Lake, Ind., to Miss Kathleen A. Webber of Chicago, November 14.

NOAH HAMPTON CHILES, Corryton, Tenn., to Miss Anadine Griffin in Louisville, Ky., December 26.

BENSON BERTHEAU ROE, San Francisco, to Miss Jane Fachtner St. John of New York, January 20.

ARTHUR W. SHAFER to Miss Lois Hein, both of Davenport, Iowa, November 24.

Deaths

Jacob Morton Mora * Chicago; University of Illinois College of Medicine, Chicago, 1925; in 1918 member of the Students Army Training Corps; assistant professor of surgery at his alma mater; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Surgery; member of the Chicago Surgical Society and the Chicago Pathological Society; fellow of the American College of Surgeons; interned at the Cook County Hospital; for many years on the courtesy staff of the Passavant Memorial Hospital; consulting surgeon, Kankakee State Hospital, Kankakee, Ill., and attending surgeon at the Mount Sinai Hospital, where he died February 10, aged 44, of dissecting aortic aneurysm with rupture due to arteriosclerosis.

Edward Quin Thornton * Philadelphia; Jefferson Medical College of Philadelphia, 1890; since 1934 emeritus professor of therapeutics at his alma mater, where in 1932 he had been appointed Sutherland M. Prevost professor of therapeutics and where he served at one time as associate and assistant professor of materia medica; member of the Pathological Society of Philadelphia; fellow of the College of Physicians of Philadelphia; associate visiting physician, Pennsylvania Hospital; author of "A Manual of Materia Medica," "Dose Book and Manual of Prescription Writing" and "Medical Formulary"; editor of Tarrard on Treatment and Bruce on Treatment; died in the Jefferson Hospital January 16, aged 78, of carcinoma of the stomach.

Roy Stanley Perkins * Lowell, Mass.; Medical School of Maine, Portland, 1914; specialist certified by the American Board of Radiology, Inc.; member of the New England Roentgen Ray Society and the American College of Radiology; served overseas during World War I; interned at the Salem Hospital, Salem, where he served as radiologist; radiologist and past president of the staff of St. Joseph's Hospital; radiologist and president of the staff of St. Johns Hospital; radiologist at the Josiah B. Thomas Hospital, Peabody, and the Tewksbury State Hospital and Infirmary, Tewksbury; died in Madbury, N. H., December 3, aged 54, of coronary occlusion.

Francis Arthur Glass * Haverstraw, N. Y.; Fordham University School of Medicine, New York, 1914; served overseas during World War I; at one time coroner of Rockland County; served as school physician in Haverstraw and since 1934 health officer of the village of West Haverstraw; chief of the medical staff of local Selective Service Board number 763; visiting physician at the New York Reconstruction Home, West Haverstraw; on the staffs of St. Elizabeth's Hospital, New York, Good Samaritan Hospital, Suffern, and the Nyack Hospital, Nyack, where he died December 14, aged 54, of coronary sclerosis.

Oscar Bruton Darden * Richmond, Va.; Medical College of Virginia, Richmond, 1918; member of the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology, Inc.; formerly vice president of the Tri-State Medical Association, composed of North and South Carolina and Virginia; associate professor of neuropsychiatry at his alma mater; in 1938 was appointed to the state advisory board on mental hygiene; on the staff of the Johnston-Willis Hospital; member of the medical staff of the Westbrook Sanatorium, where he died December 10, aged 53, of coronary occlusion.

C. Wilson West * Reno, Nev.; Rush Medical College, Chicago, 1901; past president of the Nevada State Medical Association and the Washoe County Medical Society; fellow of the American College of Surgeons; lieutenant colonel, U. S. Public Health Service Reserve; head of Procurement and Assignment of Physicians of Nevada; served during World War I; local surgeon, Western Pacific Railway Company; district surgeon, Southern Pacific Railway Company; member of the Washoe General and St. Mary's hospitals; died January 10, aged 68, of hypertensive heart disease and coronary thrombosis.

William Farquhar Shallenberger * Atlanta, Ga.; Johns Hopkins University School of Medicine, Baltimore, 1907; interned at the Johns Hopkins Hospital in Baltimore and later served as surgeon at the Hospital for Women of Maryland at Baltimore; member of the Southern Surgical Association; fellow of the American College of Surgeons; member of the Fulton County Rationing Board; at one time chief of the obstetric and gynecologic service at the Grady Hospital; on the staffs of St. Joseph Infirmary and the Piedmont Hospital, where he died December 16, aged 63, of coronary occlusion.

Thomas Luther Coley * Major, U. S. Army, retired, Bethayres, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; served during World War I; entered the medical corps of the U. S. Army as a major in 1920; served in the Philippines and in the Canal Zone; retired by operation of law on Dec. 31, 1936; life member of the Pathological Society of Philadelphia and fellow of the College of Physicians of Philadelphia; formerly on the staff of the Methodist Episcopal Hospital in Philadelphia; died January 10, aged 75, of cardiac thrombosis and gastric ulcer.

Homer Augustus Alexander * Topeka, Kan.; University of Kansas School of Medicine, Kansas City, 1914; interned at the Kansas City General Hospital; served during World War I; coroner of Shawnee County; died December 24, aged 63, of cerebral hemorrhage.

Jeremiah E. Anderson, McKee, Ky.; Hospital College of Medicine, Louisville, 1907; died in the Baptist Hospital, Louisville, December 22, aged 61, of coronary thrombosis.

Tilford T. Bailey, Port Gibson, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1892; also a druggist; died October 19, aged 88, as the result of a fall.

Charles Tomlinson Baldwin, Derby, Conn.; Bellevue Hospital Medical College, New York, 1883; member of the American Medical Association; died December 13, aged 90, of cerebral thrombosis.

Joachim Ban, West Hartford, Conn.; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultása, Budapest, Hungary, 1918; died in Boston November 2, aged 52, of coronary heart disease.

Clarence Earl Barcus, Indianapolis; Medical College of Indiana, Indianapolis, 1903; veteran of the Spanish-American War and World War I; died in the Veterans Administration Facility December 20, aged 64, of bilateral tuberculous pneumonia.

William C. Barnard * Seneca, Mo.; Marion-Sims College of Medicine, St. Louis, 1897; member of the staff of the Freeman Hospital, Joplin, where he died January 1, aged 74, of bronchopneumonia.

Charles Elton Blanchard, Youngstown, Ohio; University of Wooster Medical Department, Cleveland, 1902; died in the North Side unit of the Youngstown Hospital January 15, aged 76, following an ileocolostomy.

John R. Campbell, Somerset, Ky.; Louisville National Medical College, Medical Department State University, 1907; died December 20, aged 64, of burns received when his home caught fire.

Hiram Bryan Cloud * Wolf Point, Mont.; Chicago College of Medicine and Surgery, 1917; served during World War I; also postmaster; died October 31, aged 59, of a fractured skull received in an automobile accident and hypostatic pneumonia.

David W. Connally, Antlers, Okla.; Gate City Medical College, Dallas, Texas, 1905; member of the American Medical Association; died in St. Joseph's Hospital, Paris, Texas, November 8, aged 73, of uremia, pyelitis, cystitis and hypertrophy of the prostate.

Austin Pittenger Culbertson, Vickeryville, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; died December 23, aged 87, of heart disease.

Milton Mellon De Arman * Miami, Okla.; University of Tennessee Medical Department, Nashville, 1901; formerly mayor of Miami, member of the board of utilities and president of the Security Bank and Trust Company; on the staff of the Miami Baptist Hospital; died in the University Hospital, Columbus, November 4, aged 66, of lymphatic leukemia.

Francis Joseph Dever * Bethlehem, Pa.; Medico-Chirurgical College of Philadelphia, 1902; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; at one time instructor in medicine at his alma mater; served as chief internist at St. Luke's Hospital; died in the U. S. Naval Hospital, Philadelphia, December 30, aged 65, of bronchopneumonia.

Allen Otto Dobbins * Valparaiso, Ind.; Illinois Medical College, Chicago, 1903; formerly vice president of the Porter County Medical Society; died January 12, aged 75, of diabetes mellitus.

Benjamin Perkins Doran * Uniontown, Pa.; Jefferson Medical College of Philadelphia, 1913; served during World War I; died October 7, aged 56, of coronary occlusion and diabetes mellitus.

Luther Elliott Drew, War, W. Va.; Meharry Medical College, Nashville, Tenn., 1923; died November 24, aged 53, of pneumonia.

Winifred Smith Foster, Oakland, Calif.; Boston University School of Medicine, 1897; died in the Highland-Alameda County Hospital November 24, aged 72, of cerebral hemorrhage and a skull fracture received in an automobile accident.

John Martin Frankenburger, Kansas City, Mo.; Kansas Medical College, Kansas City, Kan., 1893; member of the American Medical Association; at one time professor of surgery and clinical surgery at the University Medical College of Kansas City; past president of the Jackson County Medical Society; at one time superintendent of the General Hospital; on the staff of St. Joseph Hospital, where he died December 25, aged 75, of carcinoma.

Samuel Orlin Gantt * Centerburg, Ohio; Starling Medical College, Columbus, 1890; died December 31, aged 83, of coronary occlusion.

James Miner Gibbons, Bismarck, N. D.; Northwestern University Medical School, Chicago, 1908; died in a local hospital November 24, aged 63, of cirrhosis of the liver.

Albert Edward Gibson, Los Gatos, Calif.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1887; died in San Jose December 8, aged 83, of a fractured right hip, shock and arteriosclerosis.

Fred Chambers Goddard, Uxbridge, Mass.; Tufts College Medical School, Boston, 1917; member of the American Medical Association; died in Milford November 7, aged 51, of coronary thrombosis.

Abram Comingo Griffith * Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, 1906; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians and member of the board of governors; major, medical reserve corps, U. S. Army, not on active duty; on the staffs of St. Luke's and St. Joseph hospitals; died in Shawnee, Kan., November 9, aged 63.

Samuel Frank Hamilton, Springfield, Ky.; Louisville Medical College, 1905; member of the American Medical Association; past president of the Washington County Medical Society; formerly county health officer; died December 31, aged 62, of carcinoma.

Frank George Heinig, Batavia, N. Y.; University and Bellevue Hospital Medical College, New York, 1925; interned at St. Vincent's Hospital of the City of New York; medical rating specialist at the Veterans Administration Facility; served during World War I; captain, medical corps, Army of the United States, not on active duty; died December 31, aged 47, of coronary thrombosis.

James A. Hill * Jefferson City, Mo.; Ensworth Medical College, St. Joseph, 1905; for many years secretary and at one time president of the Cole County Medical Society; on the staff of St. Mary's Hospital; died December 9, aged 74, of coronary thrombosis.

Otis Walter Hinshaw, Long Beach, Calif.; Rush Medical College, Chicago, 1901; formerly on the staff of the Randolph County Hospital, Winchester, Ind.; died December 12, aged 69, of cerebral thrombosis.

Henderson Looney Holman, Ozark, Ala.; Memphis (Tenn.) Hospital Medical College, 1898; member of the American Medical Association; served as chairman of the city school board and as city councilman; died December 30, aged 70, of angina pectoris.

George Edwin Houn * St. Louis; Washington University School of Medicine, St. Louis, 1913; assistant professor of clinical otolaryngology at his alma mater; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the American Otolaryngological Association; on the staffs of the Children's Hospital, St. Louis, and the Baptist Hospital, St. Luke's Hospital, St. Louis, where he died December 10, aged 66, of congestive heart disease.

Albert Huber * Kansas City, Kan.; University Medical College of Kansas City, 1904; on the staffs of the Bethany Hospital, St. Margaret's Hospital and the Providence Hospital, where he died December 4, aged 64, of coronary occlusion.

D. Columbus Hyder, Donna, Texas; University of the South Medical Department, Seawater, Tenn., 1909; member of the American Medical Association; served during World War I; for two terms secretary of the Childress-Collingsworth Hall Counties Medical Society; died October 8, aged 69, of carcinoma of the liver.

Francis Bartlett Kellogg, Los Angeles; Yale University School of Medicine, New Haven, Conn., 1886; New York Homeopathic Medical College and Hospital, New York, 1887; fellow of the American College of Surgeons; died in Pasadena October 25, aged 89.

Floyd Franklin Kirby * Waco, Texas; University of Louisville Medical Department, Louisville, Ky., 1917; formerly on the staff of the Scott and White Hospital, Temple; on the staff of the Hillcrest Hospital, where he died November 11, aged 54, of gunshot wounds of the chest and abdomen (homicide).

George C. Kolb, Cincinnati; Barnes Medical College, St. Louis, 1898; died in the Good Samaritan Hospital December 13, aged 75, of acute peripheral circulatory failure.

Orion Frank Konantz, Los Angeles; University of Pennsylvania Department of Medicine, Philadelphia, 1905; died November 29, aged 65, of heart disease.

Earl Rudolph Lehnerr * Boston; Harvard Medical School, Boston, 1931; on the staffs of the New England Deaconess and Palmer Memorial hospitals; associated with the allergy clinic of the Massachusetts General Hospital; died December 4, aged 41, of lymphoma.

Robert Willis Lenker, Schuylkill Haven, Pa.; Jefferson Medical College, Philadelphia, 1908; member of the American Medical Association; served during World War I; examining physician for the schools of Schuylkill Haven; deputy coroner of Schuylkill Haven and South Manheim township; served on the staff of the Pottsville Hospital, Pottsville; died in the Jefferson Hospital, Philadelphia, December 3, aged 64, of cerebral hemorrhage.

Eugene J. Luippold * Weehawken, N. J.; Baltimore Medical College, 1907; past president of the Hudson County Medical Society; fellow of the American College of Surgeons; on the staff of the Christ Hospital, Jersey City; past president of the Rotary Club of Union City, a director of the First National Bank and member of the chamber of commerce; died December 16, aged 58, of melanocarcinoma.

John William Malcolm, Lawton, Okla.; Kentucky School of Medicine, Louisville, 1895; died in Oklahoma City October 22, aged 74.

Salo Matheus, Buffalo; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1899; died in the Sisters Hospital December 7, aged 78, of hypostatic pneumonia and biliary obstruction.

Herbert Elliott McDowell, Spartanburg, S. C.; Atlanta Medical College, 1893; member of the American Medical Association; died October 31, aged 74.

Francis E. Mingo, Hugo, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1905; member of the American Medical Association; served as health officer of Hugo and Centerville; local surgeon for the Northern Pacific Railroad; medical examiner for various insurance companies; on the staffs of the Bethesda Hospital, St. John's Hospital and St. Joseph's Hospital, St. Paul, where he died October 29, aged 63, of cerebral hemorrhage.

Otho Lee Monroe * New York; Columbia University College of Physicians and Surgeons, New York, 1908; for many years served as instructor of otolaryngology at his alma mater; specialist certified by the American Board of Otolaryngology; on the staffs of the New York Foundling Hospital and the Manhattan Eye, Ear and Throat Hospital, where he died December 11, aged 62, of carcinoma.

Richard Mooney, Henryetta, Okla. (licensed in Oklahoma under the act of 1908); died November 17, aged 73, of heart disease.

Daniel Jackson Murphy, Vaiden, Miss. (licensed in Mississippi in 1908); died in the Jackson Infirmary, Jackson, November 30, aged 63, of cerebral hemorrhage and cardiorenal disease.

Parker Herbert Murphy * Rochester, N. Y.; Albany (N. Y.) Medical College, 1896; examining physician for local board number 544; died in the Genesee Hospital December 18, aged 76, of coronary thrombosis.

John Joseph Myers, Fallon, Nev.; College of Physicians and Surgeons of San Francisco, 1899; died in Angwin, Calif., November 29, aged 77, of cerebral hemorrhage.

Alice C. Nivison, Philadelphia; the Hahnemann Medical College and Hospital, Chicago, 1887; died in the Hahnemann Hospital December 30, aged 86, of arteriosclerotic cardiovascular disease.

Emil Zola Ossen, Quincy, Mass.; State University of Iowa College of Medicine, Iowa City, 1931; member of the American Medical Association; interned at the Sinai Hospital, Baltimore; formerly resident physician at the Norfolk County Hospital, Braintree, Mass.; on the staffs of the Quincy City Hospital, the Beth Israel Hospital in Boston and the Milton Hospital in Milton; died December 16, aged 38, of coronary artery disease.

Rowland Gardiner Paynter * Georgetown, Del.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; president of the Farmers Bank of Delaware; president of the Kent County Mutual Life Insurance Company; vice president of the Delaware, Maryland and Virginia Railroad Company; trustee of the Delaware State Hospital, Farnhurst, and the University of Delaware; died in the University of Pennsylvania Hospital, Philadelphia, December 16, aged 70, of hepatic failure.

Charles Adelbert Perry * Albany, N. Y.; Albany Medical College, 1914; served during World War I; major, special reserve, U. S. Public Health Service; chief of the department of medicine, Memorial Hospital; died suddenly December 24, aged 56, of heart disease.

Hazel Graham Petrie, Louisville, Ky.; Kentucky School of Medicine, Louisville, 1894; for many years physician for the Louisville and Nashville Railroad; died December 27, aged 72, of uremia.

Robert Harry Phillips * Lansing, Mich.; University of Michigan Medical School, Ann Arbor, 1924; at one time instructor of internal medicine at his alma mater; interned and served a residency at the University Hospital in Ann Arbor; formerly secretary of the Ingham County Medical Society; on the staffs of the Edward W. Sparrow Hospital and St. Lawrence Hospital, where he died December 19, aged 46, of posterior coronary occlusion.

Robert Simmons Phillips, Providence, R. I.; New York Homeopathic Medical College and Hospital, New York, 1900; member of the American Medical Association; died October 23, aged 71, of coronary thrombosis.

Wilfrid S. Picotte * Ishpeming, Mich.; School of Medicine and Surgery of Montreal, Que., Canada, 1896; served as president of the Marquette-Alger Counties Medical Society; for many years city health officer and county physician; served on the county board of supervisors and as president of the Peninsula Bank; trustee of the Morgan Heights Sanatorium, Marquette; died December 11, aged 70, of heart disease.

Donald Grant Ralston * McConnesville, Ohio; Ohio State University College of Medicine, Columbus, 1918; served during World War I; served as mayor, member of the board of public affairs and member and president of the county board of health; resident medical director of the Rocky Glen Sanatorium; died in Boston December 2, aged 49, of coronary occlusion.

Clarence Addison Rathbun, St. Cloud, Minn.; Bennett Medical College, Chicago, 1914; member of the American Medical Association; died in Maple Grove Township November 15, aged 53, of an accidental gunshot wound received while hunting.

Albert S. Reed, New York; New York Homeopathic Medical College and Hospital, New York, 1895; member of the local school board; died in St. John's Hospital December 14, aged 75, of heart disease.

James William Reed, Belfast, Tenn.; Vanderbilt University School of Medicine, Nashville, 1900; died in Nashville November 7, aged 71.

William H. Rentzheimer * Hellertown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1882; past president of the Northampton County Medical Society; chairman and examiner of the Bethlehem Draft Board number 3 during World War I; served for twenty-one years as secretary and director of the school district; died in St. Luke's Hospital December 6, aged 84, of myocardial degeneration and ruptured duodenal ulcer.

Calvin R. Rickenbaugh * Carlisle, Pa.; University of Pittsburgh School of Medicine, 1910; for many years a member of the board of health; on the staff of the Carlisle Hospital; died December 29, aged 58, of heart disease.

William O. Rickfort * Chicago; Rush Medical College, Chicago, 1902; one of the original members of the staff of the Evangelical Hospital of Chicago, where he died December 13, aged 69, of coronary thrombosis.

Byron Sanborn * Topsfield, Mass.; Dartmouth Medical School, Hanover, N. H., 1900; for many years associate medical examiner; since 1929 school physician; died December 20, aged 70, of coronary occlusion.

David E. Saxton, Tampa, Fla.; Eclectic Medical Institute, Cincinnati, 1883; member of the city council; died December 14, aged 93, of pneumonia.

Nicholas Julius Scarito * Lawrence, Mass.; George Washington University School of Medicine, Washington, D. C., 1912; medical examiner of the Fifth District; on the staff of the Lawrence General Hospital; jail physician; died December 3, aged 65, of coronary thrombosis.

Emil Arnold Schlageter * Chicago; Chicago College of Medicine and Surgery, 1914; associated with the Chicago Health Department as a diagnostician (supervising health officer) for many years; served during World War I; died January 18, aged 61, of tuberculosis.

Michael Joseph Shealey, Anchorage, Ky.; New York Homeopathic Medical College and Flower Hospital, New York, 1912; formerly on the staffs of various Veterans Administration facilities; served as senior physician at the Central State Hospital, Lakeland; died December 13, aged 63, of heart disease.

Wesley Morley Sherin * Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; on the staff of the Jackson Park Hospital; died December 17, aged 69, of coronary occlusion.

Alfred Dennis Simington, Philadelphia; Meharry Medical College, Nashville, Tenn., 1900; formerly on the staffs of the Veterans Administration facilities in Mobile and Tuskegee, Ala.; died October 2, aged 75, of coronary occlusion.

Justin C. Simpkins, Glasgow, Mont.; Medical College of Indiana, Indianapolis, 1896; died November 26, aged 89, of myocardial degeneration and senility.

Harold Lamberson Sippy * Winnetka, Ill.; Northwestern University Medical School, Chicago, 1928; interned at the Wesley Memorial Hospital; formerly a resident physician at the Neurological Hospital in New York; on the staff of St. Luke's Hospital, Chicago; found dead February 15, aged 44.

Alfred Hudler Smith, Springfield Gardens, N. Y.; Long Island College Hospital, Brooklyn, 1905; member of the American Medical Association; on the staff of the Jamaica (N. Y.) Hospital, where he died December 9, aged 65, of bleeding pyloric ulcer and coronary sclerosis.

Harve Bayard Spangler, Salt Lake City; St. Louis University School of Medicine, 1913; served during World War I; died in the Veterans Administration Facility November 9, aged 58, of cardiac decompensation and coronary sclerosis.

Nicholas D. Stigall, Burnside, Ky.; University of Louisville Medical Department, 1891; died December 2, aged 81, of chronic myocarditis.

Miles Edwin Stover, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1904; a member of the American Medical Association; served during World War I; died in St. Margaret's Hospital December 23, aged 70, of cerebral embolism.

Charles W. Sweeney, Bohon, Ky.; Kentucky School of Medicine, Louisville, 1900; past president of the Mercer County Medical Society; died December 19, aged 71, of coronary heart disease.

Walter Boivin Taylor * Pickerington, Ohio; Ohio Medical University, Columbus, 1902; president of the Pickerington Bank; died December 31, aged 67, of carcinoma of the liver.

Frank Carleton Thomas, Lexington, Ky.; Johns Hopkins University School of Medicine, Baltimore, 1919; member of the American Medical Association; specialist certified by the American Board of Ophthalmology; on the staffs of the Good Samaritan and St. Joseph's hospitals; died December 2, aged 49, of heart disease and hypertension.

Sam A. Thompson, Mount Vernon, Ill.; Barnes Medical College, St. Louis, 1897; member of the American Medical Association; served as president of the Association of Surgeons of the Chicago and Eastern Illinois Railroad; formerly owner and medical director of the Mount Vernon Hospital; died in the Barnes Hospital, St. Louis, December 4, aged 75, of hypertensive cardiovascular disease.

Charles B. Toms, Newberry, Mich.; Detroit College of Medicine, 1902; member of the American Medical Association; at one time secretary of the Luce County Medical Society; assistant medical superintendent of the Newberry State Hospital; died December 26, aged 69, of coronary thrombosis.

Bernard Tonsky, Philadelphia; Maryland Medical College, Baltimore, 1911; member of the American Medical Association; died in the Mount Sinai Hospital December 15, aged 61, of coronary thrombosis.

Harry Wallis Trask * West Boylston, Mass.; University of Vermont College of Medicine, Burlington, 1904; member of the American Medical Association; on the staff of the Holden District Hospital, Holden; for many years school physician in West Boylston; died November 5, aged 63.

William Henry Veenboer * Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; fellow of the American College of Surgeons; visiting surgeon, Blodgett and Butterworth hospitals; chief of staff and consulting surgeon at St. Mary's hospital, where he died December 21, aged 66, of gastric carcinoma.

A. William Vogt, New Alsace, Ind.; Missouri Medical College, St. Louis, 1884; died in the Margaret Mary Hospital, Batesville, December 3, aged 87, of carcinoma of the rectum with metastases.

John N. Volicos, Chicago; National Medical University, Chicago, 1896; died in a sanatorium in Hinsdale, Ill., December 24, aged 78, of cerebral hemorrhage and arteriosclerosis.

Matthew D. Vosburgh, St. Louis; Kansas City (Mo.) Homeopathic Medical College, 1899; died November 17, aged 80.

Della Mary Walker, Salem, Ohio; Woman's Medical College of Pennsylvania, Philadelphia, 1894; died December 23, aged 80, of hemiplegia due to cerebral accident.

Herbert Walker, Aurora, Ill.; University of Wooster Medical Department, Cleveland, 1893; fellow of the American College of Surgeons; served during World War I; died in the Veterans Administration Facility, Hines, December 9, aged 77, of carcinoma.

Claudius Meyer Warsaw, New York; College of Physicians and Surgeons, New York, 1885; also a pharmacist; served as diagnostician for the city health department; retired in 1939 as medical examiner of the Metropolitan Life Insurance Company after many years' service; died December 30, aged 84, of myocarditis.

of the Vermilion County Medical Society; served during World War I; on the staffs of St. Elizabeth and Lake View hospitals, at one time on the staffs of the Battle Mountain Sanitarium, Hot Springs, S. D., and the National Military Home, now known as the Veterans Administration Facility, where he died December 30, aged 63, of arteriosclerosis.

Bertrand K. Wilbur, La Jolla, Calif.; Hahnemann Medical College and Hospital of Philadelphia, 1891; organizer and for many years president of the Lower Merion (Pa.) Board of Health; died in the Scripps Memorial Hospital January 7, aged 75, of angina pectoris.

William Leigh Williamson, Bayonne, N. J.; New York Homeopathic Medical College and Flower Hospital, New York 1916; member of the American Medical Association; past president of the Hudson County Medical Society; physician for the Hudson County Mosquito Control Association; on the staff of the Hudson Contagious Disease Hospital, Secaucus, and the Bayonne Hospital; formerly a member of the city board of education and chief medical inspector of the public school system; died December 28, aged 68.

William Reynolds Wilson, Villanova, Pa.; Jefferson Medical College of Philadelphia, 1888; chairman of the gynecologic section of the College of Physicians and member of the Philadelphia Obstetrical Society; served as chief of the women's

CAPT. LUTHER SEXTON FORTLENBERRY
M. C., A. U. S., 1908-1944

CAPT. ALFRED M. DUSCHATKO
M. C., A. U. S., 1918-1944

CAPT. ROBERT D. MCKENZIE
M. C., A. U. S., 1910-1944

William Pinkney Webster, Oxford, Miss. (licensed in Mississippi in 1925); member of the American Medical Association; died December 14, aged 74, of heart disease.

Edward James Wheatley, Danville, Ill.; Drake University College of Medicine, Des Moines, Iowa, 1910; past president

dispensary of the German Hospital, Philadelphia, visiting physician, Lying-In Hospital, Philadelphia, and staff physician in the maternity department of the Presbyterian Hospital, Philadelphia; died in Bryn Mawr December 18, aged 81, of cerebrovascular disease.

KILLED IN ACTION

Luther Sexton Fortlenberry, Houma, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1934; member of the American Medical Association; served an internship at the Charity Hospital, New Orleans, and a residency at the Eye, Ear, Nose and Throat Hospital in New Orleans; specialist certified by the American Board of Otolaryngology; commissioned a captain in the medical corps, Army of the United States, on July 13, 1942; began active duty on Sept. 10, 1942; on entering the Army Air Corps was sent to Tarrant Field, Fort Worth, Texas, where he was assigned to Brooks Field, San Antonio, Texas, serving for two years as chief of the Eye, Ear, Nose and Throat Clinic; received overseas orders in September 1944 for the 65th Field Hospital unit, attached to General Patton's Armored Division; died in France Nov. 6, 1944, aged 35, as the result of an explosion of an enemy mine (nonbattle).

Alfred Maloch Duschatko, Scarsdale, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1942; diplomate of the National Board of Medical Examiners; interned at the Presbyterian Hospital in New York; commissioned a first lieutenant in the medical corps, Army of the United States, on June 2, 1942; began active duty on July 3, 1943; later promoted to captain; killed in action in Belgium Dec. 16, 1944, aged 26.

Robert Douglas McKenzie, Albany, Ga.; University of Rochester School of Medicine and Dentistry, Rochester, N. Y., 1935; member of the American Medical Association; formerly an intern at the Grady Hospital, Emory University Division; served a residency in otology, laryngology and rhinology at the Grady Hospital, Atlanta; commissioned a captain in the medical corps, Army of the United States, on Nov. 11, 1942; killed in action in the Southwest Pacific area Oct. 27, 1944, aged 34.

Medical Examinations and Licensure

Correspondence

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, February 24 page 483.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 26-28. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery.
ALASKA: Juneau, March. Sec., Dr. W. M. Whitehead, Box 561, Juneau.
ARIZONA: Phoenix, April 3-4. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.
ARKANSAS: * Electric Little Rock, June 7. Sec., Dr. C. H. Young, 1415 Main St., Little Rock. Medical Little Rock, June 7-8. Sec., Dr. D. L. Owens, 701 Main St., Little Rock.
CALIFORNIA: * Oral, Los Angeles, March 3. Written, San Francisco, July 9-12. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.
COLORADO: * Denver, April 3-6. Final date for filing application is March 19. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.
CONNECTICUT: * Homoeopathic, Derby, March 12-13. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven. Medical Examination, March 13-14. Endorsement, March 27. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.
DELAWARE: Examination, Dover, July 10-12. Reciprocity, Dover, July 17. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.
DISTRICT OF COLUMBIA: * Reciprocity, Washington, March 12. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.
FLORIDA: * Jacksonville, June 25-26. Sec., Dr. Harold D. Van Schaick, 2736 S. W. Seventh Ave., Miami 36.
IDAHO: Boise, July 10. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg., Boise.
ILLINOIS: Chicago, April 3-5. Superintendent of Registration, Department of Registration and Education, Mr. Philip Harman, Springfield.
KENTUCKY: Louisville, June 18-20. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville 2.
MAINE: Portland, March 13-14. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.
MARYLAND: Medical, Baltimore, June 19-20. Sec., Dr. J. T. O'Mara, 1215 Cathedral St., Baltimore. Homoeopathic, Baltimore, June 19-20. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.
MASSACHUSETTS: Boston, March 13-16. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413 F. State House, Boston.
MINNESOTA: * Minneapolis, April 17-19. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.
MONTANA: Helena, April 2-4. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.
NEW HAMPSHIRE: Concord, March 8-9. Sec., Board of Registration in Medicine, Dr. D. G. Smith, 77 Main St., Nashua.
NEW JERSEY: Trenton, June 19-20. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.
NEW MEXICO: * Santa Fe, April 9-10. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.
NORTH DAKOTA: * Grand Forks, July 3. Sec., Dr. G. M. Williamson, 4 1/2 S. Third St., Grand Forks.
OHIO: Endorsement, Columbus, April. Columbus, June. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.
OKLAHOMA: * Oklahoma City, June 14-16. Sec., Dr. J. D. Osborn, Jr., Frederick.
PENNSYLVANIA: April 10-13. Act. Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 358 Education Bldg., Harrisburg.
RHODE ISLAND: * Providence, April 5-6. Chief Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.
SOUTH CAROLINA: Columbia, June 25-27. Sec., Dr. N. B. Heyward, 1329 Blandin St., Columbia.
SOUTH DAKOTA: * Pierre, July 17-18. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, State Capitol, Pierre.
TEXAS: Galveston, June 4-6. Sec., Dr. T. J. Crowe, 918 20 Texas Bank Bldg., Dallas 2.
VERMONT: Burlington, June. Sec., Dr. F. J. Lawless, Richford.
VIRGINIA: * Richmond, June 20-23. Sec., Dr. J. W. Preston, 30 1/2 Franklin Rd., Rome.
WASHINGTON: * Seattle, July 16-18. Sec., Department of Licenses, Miss Nell Adams, Olympia.
WISCONSIN: * Milwaukee, June 26-28. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

COLORADO: Denver, March 7-8. Sec., Dr. Luther B. Starks, 1459 Ogden St., Denver.
DISTRICT OF COLUMBIA: * Washington, April 2-24. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.
FLORIDA: Deland, June 1. Final date for filing application is May 17. Sec., Dr. J. F. Conner, John B. Stetson University, Deland.
IOWA: Des Moines, April 10. Dir., Division of Licensure and Registration, Mr. H. W. Greife, Capitol Bldg., Des Moines.
MICHIGAN: Ann Arbor and Detroit, May 11-12. Sec., Miss Eloise Ielbau, 101 N. Walnut St., Lansing.
MINNESOTA: Minneapolis, April 3-4. Sec., Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis 14.
NEBRASKA: Omaha, May 1-2. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln.
OKLAHOMA: Oklahoma City, April 9. Sec., Dr. J. D. Osborn, Jr., Frederick.
OREGON: Portland, March 3. Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.
SOUTH DAKOTA: Yankton, June 19. Sec., Dr. G. M. Evans, Yankton.
TENNESSEE: Memphis, March 27-28. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.
WISCONSIN: Madison, April 7. Sec., Professor R. N. Bauer, 152 W. Wisconsin Ave., Room 834, Milwaukee 3.

ATYPICAL, VIRAL PNEUMONIA OR
VIROID PNEUMONIA?

To the Editor:—It is fortunate that lymphocytic choriomeningitis, first called aseptic meningitis, was not called atypical meningitis, or that epidemic nausea, vomiting and diarrhea (THE JOURNAL, January 6, p. 1) was never called atypical dysentery. In naming a disease or syndrome, atypical is as undesirable as the prefixes pseudo, meta or para.

Controversy on terminology may be unimportant in the face of many more pressing matters, but in regard to the disease now commonly called atypical pneumonia it is unfortunate that a better name is not generally adopted. The term primary atypical pneumonia was used by Cole in his De Lamar Lectures of 1927-1928 to include all primary forms of pneumonia clinically and bacteriologically different from typical pneumococcal lobar pneumonia. The term in this sense included pulmonary infections caused by pneumococci, streptococci, staphylococci, other bacteria and those of unknown cause. Any pneumonia, therefore, different from the clinical lobar form is atypical.

The cumbersome term primary atypical pneumonia of unknown etiology as proposed by the Surgeon General of the Army to name the disease in question conforms with this scheme if the whole term is used, but its length causes the undesirable contraction to atypical pneumonia without the necessary qualifying phrase. In Webster's Universal Unabridged Dictionary, atypical means having no type, devoid of typical character, which certainly is inappropriately applied to a disease like atypical pneumonia, now said to be by far the most important kind of pneumonia in the Army (*Am. J. M. Sc.* 209:55 [Jan.] 1945). The adjective gives rise to the use of absurd compounds like "typical atypical." In a recent paper (*Am. J. M. Sc.* 209:48 [Jan.] 1945) one author, the title of whose paper includes the words primary atypical pneumonia, avoids this difficulty by writing "a typical case of 'virus' pneumonia." I have not yet encountered "atypical atypical."

The term nonbacterial pneumonia has been used for the pneumonic forms, but again it is a negative one like atypical pneumonia and indicates something which is not. Since the first description of the disease as an entity (An Acute Infection of the Respiratory Tract with Atypical Pneumonia: A Disease Entity Probably Caused by a Filtrable Virus, THE JOURNAL, Dec. 24, 1938, p. 2377), which included both pneumonic and nonpneumonic forms of the disease, the mass of evidence has favored, but never quite proved, a filtrable virus or viruses to be the cause in most cases, and since recent experiments show that the disease can be transmitted by filtered secretions (THE JOURNAL, January 20, p. 146) why not use a positive term such as viral pneumonia, or virus-like pneumonia, or, better still, viroid pneumonia, which means the same thing? Francis (*Canad. J. Pub. Health* 35:49 [Feb.] 1944) objects to "virus pneumonia" as connoting an entity of known cause, but really it is no more definitive than the broad term bacterial or even coccal. Grammatically, the adjective form viral is preferable to virus. The adjective viroid should not offend those who still object to virus or viral pneumonia but would convey the meaning desired and, if used alone as a noun, could designate both the pneumonic and nonpneumonic forms. The use of the suffix oid (likeness or resemblance) has precedent in naming diseases such as typhoid and varioloid. Eventually, when the specific cause or causes are found, a name or names can be coined to include both pneumonic and nonpneumonic forms of the disease. The names of influenza, ornithosis and psittacosis illustrate the point, as they include various clinical forms of the respective entities. At any rate, atypical pneumonia is a poor name for the important disease now extant.

HOPART A. REIMANN, M.D., Philadelphia.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Medical Sciences, Philadelphia

208:701-830 (Dec.) 1944

*Myasthenia Gravis Treated with Large Doses of Neostigmine Methylsulfate, Intramuscularly and Intravenously, and with Neostigmine Bromide Orally. H. R. Viets.—p. 701.

Purulent Meningococcal Arthritis. W. P. Boger.—p. 708.

Sarcoidosis of Boeck: Metabolic Studies of 3 Cases. B. M. Stuart.—p. 717.

Electrophoretic Analysis of Plasma Proteins in Hyperthyroidism and Hypothyroidism. Lena A. Lewis and E. P. McCullagh.—p. 727.

Aspiration Biopsy of Thyroid in Evaluation of Thyroid Dysfunction. R. F. Lipton and M. S. Abel.—p. 736.

Cold Hemagglutinins in Primary Atypical Pneumonia and Other Respiratory Infections. By Commission on Acute Respiratory Diseases.—p. 742.

*Concomitant Administration of Sulfathiazole and Quinine or Atabrine. B. K. Harned and J. N. Etteldorf.—p. 750.

Effect of Quinidine on Mortality of Rats with Experimental Myocardial Injury. W. C. Thomas and T. R. Harrison.—p. 756.

Neostigmine in Myasthenia Gravis.—A patient with myasthenia gravis in Viets's clinic was maintained on a daily intake of twenty-five tablets (375 mg.) of neostigmine each twenty-four hours for more than two years without untoward effects. The average daily intake of 45 patients in the clinic was 163.5 mg. in twenty-four hours. These doses greatly exceed the 45 mg. usually recommended. There were no ill effects from taking these amounts. The patients did not become tolerant to the drug, and, when spontaneous remissions appeared, were able to reduce their maintenance intake quickly or to omit the drug entirely for varying periods of time. Neostigmine is relatively less toxic than was originally considered. The amount of neostigmine methylsulfate given parenterally also greatly exceeds the dose ordinarily used. One patient on entering the hospital was incapable of swallowing neostigmine bromide, and parenteral medication was begun. At first 1 mg. of neostigmine methylsulfate was injected intramuscularly every two or three hours. As this was insufficient to prevent attacks of dyspnea the dose was gradually increased to hourly injections of 1 mg. or 1.5 mg. One day he received 31 mg. of neostigmine methylsulfate. Three mg. of this total was given each day intravenously in 1,500 cc. of glucose solution. As the patient's general condition slowly improved, swallowing became possible. Three weeks after entrance to the hospital the intravenous medication was stopped and administration of neostigmine bromide orally was slowly substituted for some of the intramuscular and intravenous injections. Over a period of five weeks treatment by mouth was gradually extended until at the end of eight weeks the patient was maintained on oral neostigmine bromide, as he had been three months before entering the hospital. This was the first case in which the intravenous use of neostigmine methylsulfate was tried. It was found that the drug was well tolerated, it could be added to glucose solution, and other forms of medication could be used in the same intravenous preparation. When given over a period of hours, the same amount could be used as was given intramuscularly. Using the drip method, 1.5 mg. could be given in one hour. Subsequently, in other patients this dose has been doubled without ill effects. Use of neostigmine intravenously opens up a new field for emergency treatment and lately has been frequently adopted for this purpose. When patients are taking more neostigmine than is needed to inhibit the cholinesterase, muscular fibrillations or fasciculations will appear as evidence of cholinergic overstimulation of the muscular skeletal system.

In addition, salivation, a lowering of the heart rate and a stimulation of peristaltic activity, with or without cramps, will be noted. The symptoms of overdosage usually respond to atropine sulfate.

Concomitant Administration of Sulfathiazole and Quinine or Atabrine.—Harned and Etteldorf point out that in malarial districts the frequent necessity for the concurrent administration of antimalarials and sulfonamides would appear to demand an answer to the question of possible incompatibilities between these substances. The authors report data on the concomitant administration of sulfathiazole and quinine or atabrine to 99 volunteer hospitalized patients. The results obtained from these tests indicate that the incidence of unfavorable reactions, with the possible exception of vomiting, is not increased by the concomitant administration of sulfathiazole and quinine or atabrine. The highest doses studied were 6 Gm. of sulfathiazole daily for seven days, 2 Gm. of quinine bisulfate for the same period and 0.3 Gm. of atabrine daily for five days. The combination of drugs produced no detectable changes in the amount of hemoglobin or the total white blood count. Quinine and atabrine produced only minor changes in the free and total sulfathiazole in the blood and in the urine.

American J. Obstetrics and Gynecology, St Louis

Report of First 50 Cases of Ovarian Tumor Registry Conducted by American Gynecological Society. E. Novak.—p. 861.

Diagnosis of Cervical Cancer.—TeLinde and Galvin are concerned with the extremely early malignant lesions which are not infrequently called benign at a time when they could be cured by surgery or by irradiation. They call attention to the earliest histologic changes found in biopsies which have, in these cases, constituted the warning signal which has led to the ultimate diagnosis of cancer. One or more biopsies were taken from all of the cervixes in this series. In approximately half of the cases, several gynecologic pathologists were unwilling to make the diagnosis of cancer from the changes noted in the biopsy specimens. Since in many of the cases hysterectomy was indicated because of fibroids or functional bleeding, it was easy to make the decision to perform a total hysterectomy. In all instances the entire cervix was cut into blocks, and in many cases much careful searching had to be done before an area of actual invasion was found. In 10 out of 11 cases the authors found, after removal of the cervixes, absolute microscopic evidence of invasive carcinoma. In the eleventh case the only area of invasion was found in a biopsy specimen, but the removed cervix showed extensive changes in the surface epithelium such as were seen in the biopsies in the other cases. They do not advocate surgery rather than irradiation in these extremely early carcinomas. In the early microscopic lesions no one has had sufficient experience to be dogmatic in his preference for either surgery or irradiation. It is probable that the incidence of cures will be high by either surgery or irradiation. In this series the authors have performed total hysterectomy in all cases except 1. In this 1 exception the cervix was amputated during a Manchester operation. Following the discovery of early carcinoma in the amputated cervix, irradiation was instituted. The authors have favored surgery in order to obtain the cervix for study so as to substantiate or disprove the suspicion of cancer. Hysterectomy was favored in order to learn whether these early lesions can be cured with the conservation of one ovary. The average age of these patients was 36 years. Since the ovaries are involved late in cervical cancer, ovarian preservation may prove permissible in this group of cases. All of the 16 patients who were the subjects of this report are well, but that fact is of no statistical significance since the longest time that has elapsed since hysterectomy is four years.

Sponsored Epidemic of Mumps—Levine reports the results of an attempt to cause an epidemic of mumps in a private school of 161 children. Out of 114 susceptible children exposed 62 contracted the disease within a period of three months. Six of these developed complications. There were 4 cases of mumps encephalitis, 1 case of orchitis and 1 of probable mild pancreatitis. A questionnaire was sent out requesting complete information on the children who contracted the disease with an added question as to whether any other members of the family contracted the disease. The final analysis revealed that besides 1 teacher who was incapacitated with the disease for two weeks 10 parents suffered from the infection, a possibility which was completely overlooked when the plan was suggested. It is doubtful that any further epidemics will be sponsored by the school.

Aire-Lite: New Plastic Medium of Immobilization—Aire-Lite is a stockinet form of bandage made by loosely knitting a yarn composed of a mixture of cellulose acetate and a regenerated cellulose rayon. The knitted bandage is processed to control shrinkage, setting and drying characteristics. This processing leaves the bandage flexible and dry, in which form it is applied to the body. When the bandage is in place it is sprayed with a solvent mixture composed of a combination of volatile liquids with acetone as one of the active ingredients, which initiates setting and drying until it becomes rigid. Kulowski and his associates review observations in 136 cases in which 200 plastic casts and apparatus made with Aire-Lite were employed. The bandage must not be stretched or pulled into place because such tension will result in undue subsequent shrinkage when setting and drying have occurred. The wetted bandage should not be molded, because this will cause subsequent gelatinization and loss of porosity when the bandage has hardened. The bandage can be applied as stockinet splint or roller bandage. Users of Aire-Lite should not expect it to

replace plaster. Aire-Lite fixation in acute fractures is not wholly practicable because of the time element involved. Aire-Lite can be used effectively instead of plaster in a variety of orthopedic conditions. Aire-Lite fixation can be used also in the convalescent stages of both simple and compound fractures. Since Aire-Lite is a synthetic plastic product, atmospheric conditions may influence its behavior and interfere with uniformity of its setting and drying characteristics. One aspect of this problem is the variable tendency it has toward shrinkage and creepage, which must be anticipated and guarded against by observing a proper technique and keeping the patient under observation, especially for the first twenty-four hours after a cast has been applied. The light weight, ventilation, resistance to moisture, nonresistance to x-rays, general tidiness attending its use and acceptability to the patient gives Aire-Lite a distinct advantage over plaster.

Tubercle Bacilli in Gastric Contents—Feld states that examination of gastric contents for tubercle bacilli is practiced at the Murrdale Sanatorium of all patients who state that they do not raise sputum or whose sputum is negative. It is also used when there is doubt as to the source of the sample presented. Repeated aspirations are performed on successive days, the number varying from two to six. The material used for examination consists of undiluted gastric contents aspirated from fasting patients. Only occasionally was it necessary to do a lavage. Since 1941 only cultures have been used, and guinea pig inoculation is resorted to only in special cases. Culture results are very accurate. All specimens are cultured on three slants of Petragram's medium. In the course of a five year period a total of 4,204 gastric specimens from 868 adult patients were examined. The gastric contents of 404 of these patients were never positive, but the other 464 patients gave positive specimens. Of the 2,866 gastric examinations made on these 464 patients 1,271, or 44.3 per cent, proved positive. Cultures of concentrated sputum were made simultaneously of all patients except those without sputum. The author stresses

the importance of consecutive examinations. When five are done there is little likelihood of missing positive cases; if these examinations are negative there is not much likelihood of an active lesion. Patients who at first have only positive gastric specimens can and do develop positive sputum. The interval of repeating these examinations need not be greater than four to six months. Before patients are discharged it is necessary that they have five negative consecutive examinations.

Synovial Sarcoma.—Haagensen and Stout made tissue culture studies in their cases. The 3 tumors from which these cultures were obtained all had striking histologic characteristics. They were composed of an inextricable admixture of mesothelial cells, which often lined slits or tubes and secreted a mucicarmophilic substance with strands of active hyperchromatic fibrosarcoma-like cells associated with reticulin fibers. The relative amounts of these two cell forms varied enormously, but both of them were always present. The authors reexamined cases reported as synovioma, synovial sarcoma or by some related term. Those that did not fulfil the aforementioned criteria were rejected. This screening yielded 95 cases, to which the authors add 9 previously unreported examples. Males preponderated in the proportion of 3 to 2. The tumor may develop at any age but is most frequently found in early adult life. Nearly half of the synovial sarcomas have been found in the region of the knee joint. The initial symptom is usually pain, which may be present for several years before the tumor is noted. In 42 fatal cases the total duration varied from five months to sixteen years, the mean total duration being 5.7 years. Only 3 patients in the group of 104 have been clinically cured for more than five years after treatment. Synovial sarcoma is slow growing. Although the disease apparently remains localized for several years, metastases eventually manifest themselves in the majority of cases. Diagnosis should be established by microscopic examination of a small fragment obtained by incisional biopsy which causes the least possible trauma. Synovial sarcoma is always composed of two sharply contrasted tissue forms, one reproducing caricatures of synovial structures, the other resembling fibrosarcoma, and the two are inextricably intermingled. The treatment should be radical. The authors recommend high amputation and possibly regional lymph node dissection. There is no proof that radiotherapy is effective.

In Vitro Culture of Synovial Sarcoma.—Murray and his associates cultivated material from 3 human synovial sarcomas in vitro and compared its characteristics with similarly treated normal synovial tissue from the knee joint of the adult rat. In general the human tumor cultures parallel those from the normal rat knee joint as regards form and behavior, though the normal cultures exhibit more diversity of form and more distinctive cell types. The normal synovial cell appears to be a specific cell type distinct from other epithelium and from the fibroblast. The synovial sarcoma appears to be a distinct type of neoplasm exhibiting certain similarities to the mesothelioma.

External Pancreatic Fistula.—Miller and Wiper report observations on 3 patients with an external pancreatic fistula. The general nutritional state of these patients was directly proportional to the severity of the fistula. The first patient had experienced severe weight loss. Gradual diminution in flow of

the fistula was accompanied by increased appetite and gradual increase in weight. By the time closure of the fistula occurred, normal weight had been restored. The patient who was losing the least amount of secretion presented the least alteration of body substance. Estimates of other investigators have placed the daily amount of pancreatic flow into the duodenum in a range varying from 500 to 1,500 cc. The patient studied by the authors secreted amounts ranging up to 1,770 cc. a day. The volume flow during the daytime was greater than at night, and postprandial secretion showed a decided increase. Severe continued loss of pancreatic fluid containing large amounts of electrolytes produces changes in the plasma electrolyte pattern. Great alteration was observed in the water balance, in the plasma protein level and in the plasma sodium. The sodium loss in severe pancreatic fistulas produces a clinical syndrome similar to that described by Addison, with the exception that in these individuals adrenal disease is not present. This analogy has not been previously stressed. The administration of adequate amounts of sodium and water in the presence of sufficient plasma protein to hold them in the circulation alleviates the symptoms peculiar to this syndrome. Diminution in pancreatic secretion through the fistula may be obtained by a number of drugs, but ephedrine and sodium bicarbonate are the most practical. Detailed physiologic observations on pancreatic function support the theory that secretin secretion is a filtration process. Sodium ion is present in equal amounts in both blood plasma and pancreatic secretion. The concentrations of chloride and bicarbonate ions are the same in blood plasma and pancreatic secretion. The same amount of ionizable calcium is present in blood plasma and pancreatic secretion. Sulfanilamide is found in the same amount in blood plasma and pancreatic secretion. This suggests the use of sulfanilamide in acute inflammatory disease of the pancreas. Pancreatic flow is greatly dependent on the state of hydration of a person. Large amounts of ionizable calcium are normally returned to the gastrointestinal tract through pancreatic secretion. This phenomenon has not received the recognition it warrants. Pancreatic secretion is stimulated by the administration of histamine intramuscularly and by the intravenous administration of isotonic solution of sodium chloride or 5 per cent glucose in isotonic solution of sodium chloride intravenously.

American Onchocerciasis.—Goldman thinks that the study of American onchocerciasis, which is of great importance to public health in Guatemala and Mexico, may help to understand a closely related cutaneous nematode infection which is of some military importance at the present time, filariasis caused by *Wuchereria bancrofti*. In spite of the dissimilarities in the clinical pictures of these two forms of filariasis, there are certain broad general relationships, especially as regards reactions and response to therapy. The parasite which causes onchocerciasis is *Onchocerca volvulus*, a member of the true filaria group. The mechanism of infection of American onchocerciasis is as follows: Through the bite of an infected simuliid, the microfilariae are introduced into the skin. The infective worm travels superficially in the skin until surrounded by cellular inflammatory infiltrate, when gradually it becomes embedded in the fibrous connective tissue, where the adult worm develops. The adult forms of *Onchocerca volvulus* are present in subcutaneous nodules about the head and shoulders especially and the microfilariae in superficial tissues of skin and eye. The clinical triad of onchocerciasis includes onchocercoma, onchophthal-

mia and the nonspecific forms of onchodermatitis. The commonest type of dermatitis, perhaps, outside of pruritus, is the reddened, edematous face. The therapy is surgical removal of the nodules containing the adult worms. Present day methods of control are concerned with the treatment of the human carrier. According to some investigators there is a possibility of spread of onchocerciasis through carriers from infected areas of Central America coming into areas of the United States where the insect vector, the Simulium, is found. Moreover, the Pan American Highway traverses part of the onchocerciasis areas of Central America.

Intracranial Pressure in Human Subject at Altitude.—

Peterson and his associates studied the effects of altitude on the intracranial pressure of a patient with a large cranial defect. The tremendous size of the defect and the fact that there was no retraction of the scar made instrumental observations possible. The defect measured approximately 16 by 10 by 2.5 cm. and was perfectly healed and freely mobile under stresses of artificially increased intracranial pressure. A decompression chamber was used throughout the experiments. Preliminary decompression was carried out with a view to familiarizing the subject with the knack of maintaining the patency of the eustachian tubes and to acquainting him with the unusual surroundings of the chamber in order to reduce emotional upset to a minimum. Measurements were made at altitudes up to 30,000 feet and under conditions both of sudden and of more prolonged anoxia. The methods included (1) direct observations on a huge cranial defect, (2) herniometric recordings with photographic check, (3) plethysmographic technic and (4) recording of the spinal fluid pressure through a lumbar puncture. There was no significant increase in the intracranial pressure in man (other than normal variations) at high altitude and under conditions either of sudden or of more prolonged anoxia. These results are regarded as of particular importance with respect to transportation of casualties and sick persons by air. Experience with other patients with head injuries indicates that these casualties tolerate air transportation well. It may be to them a life saving measure by providing rapid, definitive treatment. Any specific contraindication bearing on changes in intracranial pressure is not in accord with the experimental and practical evidence obtained from the case described.

Vitamin C Economy.—Pijoan and Lozner attempted to ascertain (1) the minimal daily requirement of ascorbic acid necessary to protect against scurvy and (2) the period of protection afforded by saturation with the vitamin. The only known anatomic lesion of vitamin C deficiency is the scorbutic process, and the evaluation of ascorbic acid deficiency from an assay of the diet is untrustworthy. Not until a diet can be demonstrated to produce a steady linear decline in the vitamin C content of the white cell-platelet layer (or some index derived from whole blood) or to produce scurvy can one call it deficient. One subject was put on a vitamin C free regimen until there was a steady linear decline of the blood white cell-platelet values. He was then given at protracted intervals small amounts of vitamin until such time as the blood tissue white cell-platelet values remained constant (25 to 26 mg. per hundred grams). At the end of twenty-one months on the constantly maintained low values there were no scorbutic manifestations. An experimental wound produced in the twenty-first month was followed by adequate collagen and reticulum formation with normal tissue healing as noted on biopsy. Six subjects were saturated with ascorbic acid (400 to 500 mg. daily for four to six days) and then placed on a diet lacking in vitamin C but normal in all other respects. None of the subjects developed scurvy until five to six months had elapsed and they seemed normal in every respect until two weeks prior to the onset of the disease. Gingivitis appeared in only 1 case following the advent of perifollicular hemorrhages.

Requirements for Vitamin C and Other Vitamins.—Najjar and his associates gave to a group of 7 young adults for a period of eighteen months a diet in which all water soluble vitamins were provided as pure principles in carefully measured quantities. With the exception of thiamine, the intake of which was gradually reduced until deficiency symptoms

appeared, the vitamins were given in quantities which did not vary throughout the entire experimental period. No symptoms of any deficiency other than that of thiamine were observed. Of particular interest are the observations on ascorbic acid, which confirm those of Pijoan and Lozner that scurvy does not develop on a daily intake of from 18 to 25 mg. of ascorbic acid.

Early Vitamin Deficiency.—In the experience of Ruffin and his associates glossitis, papillary atrophy of the tongue, cheilosis and peripheral neuritis are the earliest and most reliable evidence of a B complex deficiency. All patients selected for study gave a history of an inadequate diet and had one or more of such indefinite symptoms as weakness, nervousness, anorexia, irritability or vague digestive complaints. All these patients had been ambulatory and, for the most part, carrying on their usual duties. None of them had any organic disease. There were 26 patients who were classified clinically as having a vitamin deficiency. The following studies were conducted: history, evaluation of the diet, physical examination with a neurologic consultation, blood count, total proteins, urinalysis, gastric analysis, proctoscopy and gastroscopy, ileal studies, stool fat, prothrombin time, slit lamp examination of the eyes, glucose tolerance test and determinations of vitamins A and C, carotene, nicotinic acid, riboflavin, thiamine, pyridoxine and pantothenic acid. None of the patients were found to have clinical evidence of a vitamin A deficiency; that is, there were no eye changes, night blindness or follicular keratosis. Ten patients in the deficiency group had vitamin A levels below the suggested lower limit of normal, and 7 patients had carotene levels which fell below this lower limit. Although pyorrhea was seen frequently, spongy bleeding gums, characteristic of scurvy, were not observed. There were no petechiae and the tourniquet test was negative. There were 7 patients in the deficiency group whose

blood level was below the suggested lower limit of normal, 5 of whom had no measurable vitamin C in the plasma. All patients classified as having a vitamin deficiency had clinical evidence of a B complex deficiency with one or more of the following physical findings: glossitis, papillary atrophy, cheilosis or peripheral neuritis. A comparison of the vitamin levels of the B complex in those with signs of deficiency and in the normal controls revealed striking differences between the two groups in the urinary excretion levels of nicotinic acid, riboflavin and thiamine. The greatest variations were found in the nicotinic acid levels. The levels for pyridoxine showed no significant variation between the normal controls and the vitamin deficiency group. This suggests that in deficiencies of the B complex a pyridoxine deficiency is not likely to occur.

Macrocytic Anemia in Pellagra.—Moore and his associates investigated 56 patients with macrocytic anemia observed in the Nutrition Clinic of the Hillman Hospital. These patients had existed for years on diets inadequate in animal protein and in the vitamins of the B complex. Most of the subjects had clinical evidence of pellagra, arboflavinosis or beriberi. In 25 the red blood cell count ranged from 1 to 3 million cells. Males predominated in a ratio of 3 to 1, and most of the patients were older than 50 years of age. Clinical manifestations were weakness, pallor, glossitis and intermittent or persistent dermatitis. The skin either showed the presence of pellagrous dermatitis or was rough, hyperpigmented and dry. The peripheral blood and bone marrow were cytologically indistinguishable from those of Addisonian pernicious anemia. Free hydrochloric acid was found in the gastric contents of 16 patients at the time they were first studied; in 5 others, free acid was found on subsequent examination. All of the subjects showed (1) pro-

therapeutic response to the parenteral injection of highly purified liver extracts and (2) reticulocyte rises when fed beef muscle, and 80 per cent alcoholic extract of beef muscle or crude liver extract. When the oral administration was prolonged, the red blood cells also increased in number. The anemia is probably caused by a dietary deficiency of extrinsic factor associated in many, but not all, instances with poor absorption from the intestinal tract. Inadequate production of intrinsic factor is probably also a contributing influence. Thiamine, niacin, riboflavin, calcium pantothenate, pyridoxine, inositol, para-aminobenzoic acid and choline given together both orally and parenterally did not affect the erythropoietic equilibrium.

Clinical Studies of Influenza Epidemic.—Shrader presents the clinical characteristics of an outbreak of an acute febrile disease with generalized symptoms which occurred and spread with explosive rapidity among the 508 members of two companies of the A. S. T. Unit at St. Louis University in November 1943. Members of Companies A and B had returned from furloughs by the night of November 7. On the morning of November 9 a man from Company B reported to sick call with the clinical picture of what in the previous weeks had been diagnosed as influenza. On the morning of November 10 a man from Company A reported to sick call with a similar clinical picture. On November 12, 32 men with this disease reported to the student health service throughout the day; 25 of the 32 cases were from Company A. With the hope that the spread of the disease might be restricted, Company A was quarantined on the night of November 12. On November 13 there were only 6 new cases, but on November 14 there were 36 new cases (14 in A and 22 in B). This rapid spread in both companies suggested a disease of very short incubation period. The author believes that the disease was spread primarily by class groups and secondarily through building associations and contacts. The disease was highly infectious, with an incidence of as high as 49.1 per cent in one class group and 44.4 per cent in one building. Infectiousness persisted in the postfebrile period for about three days. The incubation period was probably between twenty-four and forty-eight hours. The disease had a four day febrile course without local signs, local symptoms or complications. Because of the short incubation period, the high degree of infectiousness, the freedom from symptoms during the early invasion period and the presence of subclinical cases, the most effective method of control seemed to be case finding inspections twice daily. These inspections consisted of taking temperatures, observing the men and questioning them as to their well being. All men with fever or those who felt ill were either hospitalized or isolated for further observation. The case finding inspections were continued from November 15 to November 22, during which time all activities in both companies were suspended and the men were restricted to their building areas. The duration of the disease and the degree of illness were effectively lessened by early discovery and prompt rest. No other form of treatment seemed to have any effect.

Peptic Ulcer and Nutrition.—Considerable evidence has accumulated that a dietary deficiency may play a part in the development of peptic ulcer. Cheney states that in many patients symptoms first appeared after being on canned rations, which included little or no fresh food for weeks or months. Meulen-gracht's dietary management makes use of the principle that a full diet will improve the patient more rapidly than a restricted one. In the production of experimental peptic ulcer in dogs it has been shown that the lesion is less readily produced if the dog is on a full diet than when the animal is on a restricted diet. In experiments with chicks it was found that dietary deficiency and cinchophen produced gastric ulcers which could be prevented or ameliorated by feeding a diet which contained an antigizzard erosion or antiulcer factor which has been designated as vitamin U. The effectiveness of a high caloric diet rich in this antiulcer factor was investigated in the management of a group of patients with peptic ulcer which had been recalcitrant to treatment. The dietary regimen was based on the usual convalescent ulcer diet with the addition of certain food substances known to contain the antiulcer factor. The diet included six eggs daily, two soft boiled for breakfast and four uncooked in egg nog between meals. Fifty Gm. of butter, 30 Gm. of peanut butter, 30 cc. of olive oil and certain fresh greens also were included. The patients also received one helping of tender meat and orange juice and tomato juice daily. The liberal diet made no patient worse, and the omission of the drugs did not aggravate the patients' symptoms. Two thirds of the patients were completely relieved, and 27 of the 31 patients were clearly benefited. The patients represent a small number of cases of therapeutic failures encountered in a large series of ulcer patients treated by the usual medical management, and consequently the successful results must be considered exceptional. This group of 31 patients represents but 7.4 per cent of the 418 ulcer cases observed, and it is just this group

which has so frequently been operated on in the past. It is recognized that defective nutrition is but one factor of several which may lead to the precipitation of symptoms of peptic ulcer, but it would seem that it might be an important one.

Early Hepatic Cirrhosis.—Johnson says that a relative increase in globulin may be expected in the majority of patients with early cirrhosis of the liver. Other diseases which exhibit alteration in the serum proteins must be considered in the differential diagnosis. He reports 5 cases with definite evidence of increase in globulin, symptoms of liver dysfunction and decreased hippuric acid excretion. These cases are probably illustrative of early hepatic cirrhosis, in which stage adequate treatment is most effective. A high carbohydrate, high protein and low fat diet with extra vitamins has caused great symptomatic improvement.

- *Fluoride Domestic Waters and Systemic Effects: II. Fluorine Content of Urine in Relation to Fluorine in Drinking Water. F. J. McClure and C. A. Kinser.—p. 1575.

Fluorine Content of Urine in Relation to Fluorine in Drinking Water.—McClure and Kinser found that where domestic waters are free of fluorine the fluorine present in urine averages 0.3 to 0.5 part per million. An increase of fluorine in the urine was associated with the use of domestic waters containing as little as 0.5 part of fluorine per million. Fluorine in urine specimens continues strikingly proportional to the fluorine content of the drinking water through the range of 0.5 to 5.1 parts of fluorine per million in the domestic water. The results furnish additional evidence of the importance of water borne fluorine as a source of fluorine in human diets. The data agree with previous epidemiologic studies which have demonstrated a striking relation between fluorine in communal water supplies and dental health, including reduced incidence of dental caries in 12 to 14 year old children. The close correlation between fluorine in drinking water and the fluorine content of urine suggests that the presumed hazard of cumulative toxic borne fluorosis surrounding certain water borne sources of fluorine in the United States is greatly reduced by this relationship. An efficient urinary elimination of fluorine appears to be characteristic of persons residing in certain fluoride areas of the United States where the drinking water contains 0.5 to 5.0 parts of fluorine per million. The metabolism of fluorine under these conditions seems to be a normal function of the human body and seems characterized by a condition approaching metabolic equilibrium, at least in the adult organism.

Treatment of Fissured Nipples with Vitamin A and D Ointment.—During two years of study, a group of 100 postpartum patients who complained of pain and tenderness of the nipples, with or without grossly demonstrable fissures, were treated with local dressings of vitamin A and D ointment; second group of 200 postpartum women had regular prophylactic dressings of vitamin A and D ointment applied to the nipple immediately after delivery and throughout the puerperal period; a third group of 200 postpartum patients had routine prophylactic care of the nipples with local measures other than vitamin A and D ointment. It was found that the use of vitamin A and D ointment in the local care of the puerperal nipple gave protective and therapeutic results much better than those obtained by other methods.

Neostigmine in Acute Anterior Poliomyelitis.—Eveleth and Ryan report 200 cases of acute poliomyelitis in the New Haven Hospital from June through November 1943. They felt justified in trying neostigmine. The Kenny method was used in the treatment of all patients. Twelve patients in the early stages of the disease received neostigmine as an additional form of therapy. The 12 patients all showed severe spasm of the back muscles and hamstrings, and 10 of these had some paralysis in the legs. The average period from the onset of symptoms until neostigmine was given was eighteen days, and the patients averaged two weeks of the Kenny treatment during this period. The procedure was as follows: 1. The range of passive motion of the involved extremity was measured by means of the goniometer. 2. A subcutaneous injection of neostigmine methylsulfate was given. 3. The range of motion was again measured after one hour. 4. Routine Kenny treatment was then resumed. 5. Neostigmine was given orally three times a day for twenty-eight days. 6. The range of passive motion was measured for the third time. The doses of neostigmine and of atropine given were approximately the same as those used by Kabat and Knapp. There was a definite relief of muscle spasm, as indicated by an increased range of passive motion, in the lower extremities following the initial subcutaneous injection of neostigmine methylsulfate. This decrease in spasm occurred in all 12 patients and was recorded one hour after the injection. During this hour no packs were used. The difficulty in determining the effect of the oral administration of neostigmine on muscle spasm after the four week period is obvious. These patients might have had a decrease in muscle spasm without any therapy during this period, or the hot packs may have relieved the spasm. After a period of four weeks of neostigmine given orally there was, in general, little further decrease in spasm. Six of the 12 cases showed less spasm. The authors were not able to note the effect of neostigmine in contractures because their patients were all in the early stage of the disease. A period of about eight months has elapsed since this study was made and these patients have continued to receive the Kenny treatment without neostigmine. They have shown a gradual relief of muscle spasm and in most cases an improvement in muscle power. Whether or not this relief was facilitated by neostigmine is difficult to determine.

 *Aspects of "Fibrositis." T. A. Elliott.—p 22
 Case of Tuberculous Rheumatism (Grocco Poncet Type). E. Montuschi.—p 26

Fibrositis.—Elliott shows that the conception of fibrositis introduced in its present form by Sir William Gowers in 1904 provided so ready an explanation for a number of otherwise knotty problems that it was and is widely accepted as a disease, although it has never been placed on a satisfactory pathologic basis. The skepticism born of this pathologic ambiguity is increased by the circumstances that many conditions formerly viewed as typical examples of fibrositis are now known to have other cause. Many cases of lumbago, sciatica and "brachial neuritis" are due to prolapse of the nucleus pulposus. Other cases of lumbago are examples of spondylolisthesis or the reverse condition of posterior displacement of the fifth lumbar vertebra. Nevertheless the aforementioned conditions are still frequently treated as fibrositis. From a review of personal mistakes of this type it appeared to the author that among the factors which contribute to this confusion the most common is the misinterpretation of tenderness as a physical sign. He shows that, apart from a hypothetical inflammatory origin, muscle tenderness may have two explanations. The first is the traditional one—a central lowering of threshold to sensory stimuli. The second is the effect of localized involuntary spasm arising reflexly from lesions elsewhere. This spasm is accompanied by an increased irritability and occurs in extensor muscles which are anatomically or physiologically related to the site of disease. Thus a prolapsed disk in the lumbar spine may give rise to spasm in the lumbar muscles and it may also cause spasm of muscle fibers in the buttock and calf by irritating the fifth lumbar root. Such spasm contributes pain to the patient's discomfort, and this may be relieved by measures taken to reduce the spasm. Such treatment is valuable, but the elimination of pain by local injections of procaine does not necessarily exclude a central lesion of the nerve roots or spinal column. This thesis does not seek to shut the door on fibrositis as a clinical entity. It would be unfortunate if the hypothesis of myofascial inflammation was to be replaced at this stage by a facile generalization that muscle tenderness is always due to spasm of skeletal muscle.

Snake Venom Ophthalmia.—According to Ridley, *Naja nigricollis*, the black necked cobra, is the common spitting snake, though other African cobras have to a less extent the power to eject venom. All these snakes are exceedingly poisonous. The author reports that a laborer aged 30, while cutting grass with a native scythe, discovered a snake. The reptile spat venom, some of which entered the right eye. About twenty minutes after the injury the man walked into the ophthalmic department of a hospital, accompanied by one of his colleagues carrying the decapitated snake, which was identified as a black necked cobra. The patient complained of considerable pain in the right eye. There was a moderate degree of conjunctival

injection. The whole corneal epithelium was edematous. On the second day there was chemosis with a profuse mucoid discharge accompanied by edema of the lids. The lower half of the cornea was bare of epithelium, but sensation was absent. By the fifth day the cornea was completely covered by edematous, very loosely attached epithelium. Sensation was present, though much diminished. On the ninth day corneal sensation was normal but the bulla remained. On the fourteenth day the epithelium was normal and apart from the localized faint corneal opacity the eye had completely recovered. The interesting features of this case appear to be the prolonged corneal anesthesia, persisting for five to seven days, and the abnormal epithelial regeneration resembling the epitheliolysis of neuro-paralytic keratitis or recurrent erosion. Cobra venom has been used as an analgesic, but little work has been done on the employment of venom in ophthalmology. The author suggests that a harmless substance capable of producing prolonged anesthesia of the anterior segment of the eye would be of considerable value in inflammatory conditions and after operations or other forms of trauma, and the styptic effect of viper venom might also have its uses.

Pulsator Treatment of Crush Injury.—Marshall reports 4 cases of crush injury in which unexpectedly good results were obtained with a respirator. As soon as possible after the diagnosis of crush injury had been made, the damaged limb or limbs were placed in the respirator and the pulsation mechanism was worked at the slowest rate for about half an hour. Four patients received treatment for this period every two or three hours in rotation. It was continued regularly, except during sleep, until the circulation of the affected parts seemed restored, as judged by the diminution of pain, return of warmth and color and loss of tension. They all recovered. The author concludes that the fatal result of crush injury may be prevented by prompt restoration of the circulation in the affected part by the use of a mechanical pulsator.

Quinine Blindness.—A man aged 37, who had developed malaria twelve years before in India and who often had had quinine without toxic effects except tinnitus and transient deafness, in a recent attack was given about twelve doses of 30 grains (2 Gm.) of quinine dihydrochloride in one day. He is now blind. McGregor and Loewenstein say that, if such unfortunate results are to be avoided, the view that quinine blindness is benign must be modified. The authors present evidence of damage to the retinal cells by quinine with the production of a scotomatous or "sievelike" field. The milky appearance of the retina is attributed to the ischemia produced by toxic swelling of the endothelium of the small vessels. Treatment is designed to effect early and vigorous fluid exchange—locally, by paracentesis of the cornea and emptying of the anterior chamber for the first few days, at least in one eye; generally, by purgation and copious drinks, intravenous saline solution and thecal drainage. The processes of oxidation in the retina should be facilitated by a generous intake of vitamin B complex and ascorbic acid. To avoid such catastrophes as blindness, quinine dosage should be cautious and the drug should be stopped at once if visual symptoms arise.

Micromethod of Estimating Penicillin in Blood Serum and Other Body Fluids.—Fleming points out that there is no chemical test for penicillin in blood, but the concentration of this substance in blood serum can readily be estimated by titrating its bacteriostatic power on a suitable test organism. Since it is inadvisable to withdraw large specimens of blood when the withdrawal has to be repeated frequently, the author prefers microtitration, which has been constantly improved. The hemolytic streptococcus has been substituted for the staphylococcus as the test organism. Blood is used as the indicator, and for incubation of the test mixtures either slide cells or capillary tubes are used. The author gives detailed descriptions of the slide cell method and of the capillary tube method. Very consistent results are obtained by these methods, and when a series of observations is made at intervals following an injection of penicillin a regular curve is obtained.

Penicillin Content of Blood Serum.—Fleming and Young estimated the concentration of penicillin in the blood serum of patients who have been receiving the drug in various doses intravenously, intramuscularly or subcutaneously, either as single injections or as a continuous drip. In this way they acquired information as to the maximum height to which the penicillin content rose and as to how long an appreciable penicillin content was maintained after a dose. The curves are regular, which suggests that the method of test is reasonably accurate. These curves show that penicillin is very rapidly absorbed after intramuscular or a subcutaneous injection and that following the larger doses it can be detected in the blood for a considerably longer time than after the smaller doses. Penicillin appears in the blood within a few minutes of an intramuscular or subcutaneous injection; so from the point of view of getting the drug into the circulation quickly there is little to be gained by intravenous administration. At the same time there is little to be lost, for the rate of disappearance from the blood is not greatly

different whether the injection is given intravenously or intramuscularly. The information obtained indicates the frequency with which doses should be given to maintain a bacteriostatic concentration in the blood over the whole period of treatment.

Prognosis in Schizophrenia.—Stallworthy thinks that schizophrenia is sufficiently common in general practice to make valuable some broad generalizations about its prognosis. Of 775 patients admitted to the Auckland Mental Hospital in 1939 and 1940, 196 were considered schizophrenic. The author investigated the outcome in these patients and found that in patient develops a psychosis which fits the somewhat accommodating label of schizophrenia he has a remarkable chance of recovery. Forty-two per cent of schizophrenic patients admitted to the Auckland Mental Hospital are, after four years, discharged; some of them show intellectual and emotional blunting, but many are completely well. Seven per cent of the remainder are dead—scarcely a negligible mortality. In spite of occasional dramatic responses there is no unquestionable evidence that modern assaults on the cerebrum with convulsant drugs, electricity or the surgeon's knife materially improve the long term outlook in schizophrenia. In the Auckland Mental Hospital chief reliance is placed on the minimal emotional demands of an ordered institutional existence and the extracerebral stimulus of occupational therapy. In a patient with schizophrenia, neither intellectual deficiency, a tainted family history, the occurrence of previous psychotic episodes, relatively long duration of symptoms nor type of illness is necessarily incompatible with recovery. If recovery is to occur, it is not to be expected for six to nine months.

Latent Anaerobic Infection in Gunshot Wounds.—Chernaya studied the anaerobic flora cultured from 159 bone sequestrums, 92 foreign bodies removed from old gunshot wounds and tissues from 34 reamputated stumps. Anaerobic flora was found in 16 of 34 reamputations, in 32 of 92 foreign bodies and in 39 of 159 bone sequestrums. The clinical course of the investigated cases did not differ from the usual and did not give any reason to suspect the presence of anaerobic microorganisms. The lapse of time between the sustaining of the wound and the bacteriologic investigation amounted to eight to sixteen months and in some instances to as long as fourteen to sixteen months. *Clostridium welchii* was found in 51 instances and *Clostridium sporogenes* in 43, while in 7 instances non-pathogenic anaerobes were demonstrated, in 5 *Clostridium butyricum* and in 2 *Clostridium tetanoides*. Other causative agents of gas infection, such as *Clostridium oedematiens*, *Clostridium septicum*, *Clostridium histolyticum* and *Clostridium tetani*, were not demonstrated in any instance. Seventy-five per cent of the strains of *C. welchii* have retained their virulence. Prolonged residence up to sixteen months of this organism in the body did not alter its cultural or pathogenic property. The author concludes that the satisfactory general state of a patient with an old gunshot wound does not exclude the possibility of a dormant latent anaerobic infection which may become activated by a new intervention.

Book Notices

Control of Pain in Childbirth: Anesthesia, Analgesia, Amnesia. By Clifford B. Lull, M.D., F.A.C.S., Clinical Professor of Obstetrics, Jefferson Medical College, Philadelphia, and Robert A. Hingson, M.D., Surgeon, U. S. Public Health Service. With an introduction by Norris W. Vaux, M.D., Obstetrician-in-Chief, Philadelphia Lying-In Unit, Pennsylvania Hospital, Philadelphia. Cloth. Price, \$7.50. Pp. 356, with 132 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1944.

In this book the authors present two basic themes in the control of the pains of labor, namely the relief of pain by the encephalic approach, i. e. obliteration of pain at the site of interpretation, with general, intravenous, intramuscular and rectal forms of amnesia, analgesia and anesthesia, and by the anatomic approach through the obliteration of painful stimuli at their site of origin through various forms of regional, local and spinal anesthesia and caudal analgesia.

Because there is no single form of pain relief suited for every case, the authors have borrowed valuable information from other sources, particularly from John S. Lundy, C. O. McCormick and L. H. Maxson. In addition, special sections were prepared: on direct infiltration anesthesia in obstetrics by J. P. Greenhill, on parasacral, pudendal and infiltration anesthesia in obstetrics by B. E. Tucker and H. B. W. Benaron, on the technic of local anesthesia for cesarean section by Charles Gordon and on x-ray studies of the sacrum and sacral hiatus by P. A. Bishop.

Many subjects are covered in this book, including the anatomy of the organs of parturition, physiopharmacology of the general anesthetic, amnesic agents, paravertebral, peridural, regional, local, spinal, caudal and continuous caudal analgesia and anesthesia in obstetrics, psychology of the management of pregnancy and labor, history of pain relief in childbirth, technics for the relief of pain during labor and delivery, management of the third stage of labor, cesarean section, management of the puerperium, choice of the agent of pain relief in home obstetrics, control of pain in maternal complications and methods and drugs used in the resuscitation of the newborn.

The book is well written and contains numerous illustrations. Most of the illustrations, although borrowed from other sources, are highly instructive, particularly the unique illustrative charts prepared by D. Andrassy which graphically portray the depressive and stimulating actions of different drugs on maternal and fetal organs. At the end of each chapter is a useful bibliography. Regardless of whether or not one agrees with the authors in their enthusiasm for continuous caudal analgesia, all obstetricians and anesthetists can read this book with great benefit.

Terapéutica ginecológica. Por Carlos J. Calatront, docente libre de clínica ginecológica (Buenos Aires), y Vicente Ruiz, profesor titular de clínica ginecológica (La Plata). Third edition. Cloth. Price, \$45 M/Arg. Pp. 1,212, with 412 illustrations. Buenos Aires: Librería y Editorial "El Ateneo," 1944.

This is a large and impressive volume. It is well printed, the style is good, it is easy to read and it is clearly and profusely illustrated. The majority of illustrations are original and many are in color. This work is the result of a lengthy association of the authors with students of clinical gynecology, both as instructors and as consultants. The aim has been to publish a book of gynecologic therapeutics dedicated especially to the general physician. For each gynecologic disease the authors have summarized its essential anatomopathologic lesions, its symptomatology and its diagnosis, thus laying a foundation for the most suitable therapy.

The volume discusses the normal menstrual cycle, anomalies of the menstrual cycle and treatment of pseudoamenorrhea, amenorrhea and dysmenorrhea, metropathia hemorrhagica, genital hemorrhage, abortion, ectopic pregnancy, genital discharges, gonorrhea, myoma, ovarian tumors, endocrine and nonendocrine ovarian insufficiency, genital hypoplasia, genital tuberculosis, pelvic sepsis, hydatidiform mole, chorionepithelioma, endometriosis, uterine displacement and prolapse, genital echinococcus, genitourinary fistulas and carcinoma of the vulva, vagina, cervix uteri and endometrium, and gynecologic radium therapy.

The full series of the League of Nations cancer of the cervix classification is shown in color plates. This will aid in the more accurate classification of cancer of the cervix. The fullest possible dissemination of such knowledge among general practitioners will bring the recognition and treatment of cancer of the cervix patient to a higher level than has at present been attained. The authors are to be commended for placing this classification in such a widely distributed, easily available textbook.

Chapters dealing with menstruation and its anomalies are long and thorough. The authors have presented the subject thus deliberately, believing that a more efficacious treatment of menstrual disorders should be given by the general practitioner. Rectal gonorrhea is discussed in some detail, since the bibliography in Spanish on this subject is extremely scanty and since it constitutes an only moderately known localization of the organism.

In all chapters theoretical discussions, the listings of hypotheses and bibliographic citations have been carefully avoided. The authors have presented the most acceptable current opinion as taught in the gynecologic clinics of Buenos Aires and La Plata. They have offered a practical point of view to the general physician and a fund of facts which in Spanish can be found only scattered through pamphlets and publications not always within his reach.

The most recent advances of gynecologic thought, the use of chemotherapy in infections, the fuller knowledge of endocrine functions and the use of artificial estrogens are included.

The chapters on neuropsychiatry in gynecology and on diet are new with this edition. For the notes on the mental impact of gynecologic disease the authors are to be particularly commended. This chapter was contributed by Dr. Jorge Thenon. The chapter on diet was written by Dr. Landebure.

Dr. Rudolpho Sammartino prepared the anatomopathologic specimens, from which Mr. Julio Rodriguez revised the prescriptions which accompany the text. Dr. Juan C. Ahumado, titular professor of clinical gynecology in the faculty of medical sciences of Buenos Aires, wrote the preface and gave his approval of the material herein presented.

Surgery: A Textbook for Students. By Charles Aubrey Pannett, B.Sc., M.D., F.R.C.S., Professor of Surgery, University of London. Cloth. Price, 35s. Pp. 740, with illustrations. London: Hodder and Stoughton, Ltd., 1944.

Much of the glamour and enthusiasm which accompany the first appraisal of any new book is lost in this case. The war effort is no doubt responsible for the quality of paper and binding used in this volume. However, the subject matter which it contains soon reveals its true worth. The author has made excellent use of a small number of illustrations and diagrams. They are of prime importance in any textbook on surgery, especially when it is written for students. The individual topics are well segregated in the text. This makes for a clearer understanding and a clearer reference availability.

It is unusual for one writer to attempt to cover the entire subject of surgery. This may result in the presenting of only one view on a controversial subject. The student especially should know that there are other and good methods and procedures in surgery. The disparaging remarks made concerning the use of the McBurney incision in appendectomies is an example. The substitute incision offered might not be so successful in other hands. The statement concerning the frequency with which chronic ulcers of the stomach are found on the posterior wall would be questioned by some. Radium alone as a treatment for carcinoma of the breast except in well advanced cases would be questioned.

Scrubbing the wound with soap and water is not sanctioned by the author in cases of compound fractures. This procedure is used by many surgeons who feel that irrigation of the wound with sterile saline solution in large quantities removes the danger of contamination which may have been carried into the wound. Infection from drinking water being considered as a factor in the production of goiter is not in agreement with the current opinions as to the cause of pathologic conditions of the thyroid.

In the discussion of bowel obstruction and resection, instruction as to the benefit of the Wangenstein constant suction appa-

ratus and the Miller-Abbott tube would be of great value. More reference to the value of the sulfonamide drugs and penicillin in combating various infections, especially gonorrhea, would be appreciated in a publication appearing at this time. The author's methods of treating fractures of the femur have shown excellent results among war casualties. The outline of the text to follow which is placed at the beginning of some of the chapters is especially helpful. A textbook of this recent date could well include some mention of the Rh factor in blood groupings and transfusions. The absence of a discussion of pathologic and physiologic processes in reference to surgery is noticed. The omitting of surgical consideration of the ear, nose and throat specialty and of gynecology is explained on the basis of their being too technical for a general surgeon.

The book fulfils its purpose as a textbook for students: it gives valuable information on many subjects.

The South African Frog (*Xenopus laevis*) in Pregnancy Diagnosis. By Abner I. Weisman, M.D., Adjunct Gynecologist, Jewish Memorial Hospital, New York, and Christopher W. Coates, Aquarist, New York Zoological Society. Aided by a Grant from the New York Biologic Research Foundation, New York. [Including] Supplement: Queries Relating to *Xenopus laevis*. Cloth. Price, \$2. Pp. 134, with 47 illustrations. New York: New York Biologic Research Foundation, 1944.

This monograph gives a concise exposition of the life of the South African frog and its care for laboratory use in the diagnosis of pregnancy. However, almost half of the volume is taken up with the historical account of the recognition of the importance of this frog in scientific studies and its geographic distribution as well as its life cycle and habits. This section should be of interest to zoologists and laboratory caretakers who require this information for the proper sustenance of normal frogs. The latter part of the volume is of value to clinicians because of the use of this type of frog for pregnancy diagnosis as well as for the pathology of pregnancy (hydatidiform mole, chorioepithelioma) and endocrinopathies. The test is simple and has a high degree of accuracy (98-99 per cent). The only difficulty in using this test is the care of the frogs, because they require special consideration as to proper temperature, water changes, tank space, frequent cleansing and proper isolation with the first appearance of any disease condition. In good laboratories all these requirements can be met; nevertheless these frogs are not as hardy as mice, rats or rabbits for the pregnancy tests in this country. The American frog (*Rana pipiens*) is unsuitable for the pregnancy test.

The advantages of the *Xenopus* frog test are that the test is speedy (six to twelve hours), the test is accurate (98 to 99 per cent), the test is simple to perform, requiring one single subcutaneous injection, the frogs are easy to maintain, according to the author, the test is inexpensive since the animals can be used repeatedly, and the end reaction is the simple observation of eggs in water. The great value of the test is in ectopic pregnancy when speedy and accurate pregnancy diagnosis is imperative. This little book is well written and therefore easily read. It has much information about *Xenopus laevis*, its value to laboratory investigations, the comparative study of the various pregnancy tests and the use of the frog in pharmacologic as well as endocrine studies. An interesting supplement contains questions directed to workers with a new test and the answers.

A Laboratory Manual of Physiological Chemistry. By D. Wright Wilson, Benjamin Rush Professor of Physiological Chemistry, University of Pennsylvania, Philadelphia. Fifth edition. Cloth. Price, \$2.50. Pp. 269. Baltimore: Williams & Wilkins Company, 1944.

As Dr. Wilson's preface states, this is a teaching manual in the laboratory practice of physiologic chemistry and not a comprehensive reference book. An introductory section comprises experiments illustrating fundamental chemical laws and those aspects of the organic chemistry of carbohydrates, fats and proteins important to the biochemist. The second section of the book contains experiments concerned with the chemical nature of body tissues and fluids and includes the material on qualitative and quantitative blood and urine analyses usually taught in medical courses in biochemistry. There are also a number of experiments designed to demonstrate the various dietary deficiencies in laboratory animals. The alternate pages of the book have been left blank so that the manual can be used as a *laboratory notebook*. The practical and continued value of the manual is attested by this being the fifth edition.

Hypertension and Hypertensive Disease. By William Goldring, M.D., Associate Professor of Medicine, New York University College of Medicine, New York City, and Herbert Chasis, M.D., Assistant Professor of Medicine, New York University College of Medicine. Cloth. Price, \$3.50. Pp. 253, with 53 illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1944.

The authors of this book are definitely committed to the view that so-called essential human hypertension is not primarily of renal origin. They believe that the initial cause of this type of hypertension is some unknown humoral agent which brings about the generalized vasospasm that determine the elevation of blood pressure. The organic vascular disease, including the intrarenal and generalized arteriosclerosis so frequently found in association with essential hypertension, they consider to be secondary to the same humoral mechanism that initiates the hypertension. They admit that even in man hypertension may be of renal origin, but only when the renal disease is known to be primary. The renal vascular disease of essential hypertension they do not regard as primary. The various arguments, including the evidence presented by the recent work on experimental renal hypertension, now adduced in favor of the primary renal origin of human hypertension, fails to convince these authors, even though they themselves have shown that the only changes seen in early human essential hypertension are disturbances of renal hemodynamics and excretion. These changes they attribute to efferent glomerular arteriolar spasm, which they consider part of the generalized vasoconstriction initiated by the unknown humoral mechanism. This book is an important contribution to the literature on human hypertension. It deals largely with the work of Homer W. Smith and his collaborators, in which the authors are included. Both the body of the book and the appendix give full details about their views, methods and important contributions to the study of renal hemodynamics and excretion. Included are excellent chapters on the surgical and medical treatment of human hypertension giving full details about the management of the patient with this condition.

The Microbiology of Foods. By Fred Wilbur Tanner, Ph.D., D.Sc., Professor of Bacteriology and Head of the Department, University of Illinois, Urbana. Second edition. Cloth. Price, \$12.50. Pp. 1,186, with 5 illustrations. Campaign: Garrard Press, 1944.

The extensive compilation of information on the relationship of micro-organisms to foods as found in this edition attests the competence of the author in this field. The early chapters present the fundamentals of food preservation and a detailed discussion and classification of the organisms found in foods. Following this the author considers the microbiology of fresh and canned foods, including water. For each food there is extensive coverage of the subject with respect to normal flora of food, use of microbes in food processing, spoilage action and consideration of methods used to combat spoilage. Disease transmission is discussed where this possibility exists. There is a wealth of technical information throughout on methods for bacteriologic examination, identification of organisms and preparation of culture mediums. Official standards of purity and methods of examination are included where they exist. One section is devoted to the microbiologic assay of foods for vitamin content. The book serves an excellent purpose as a source of detailed technical information on facts and methods. It is a valuable reference source on the broad subject covered by its title, since nearly all facts quoted are supported by references, most of which are recent, and bibliographic lists follow each chapter. Its usefulness should be greatest in the teaching of technical courses dealing with food handling and in industrial food laboratories.

A Study of Variations in Output. By S. Wyatt. Assisted by E. Marriott, W. M. Dawson, D. E. R. Hughes and F. G. L. Stock. Medical Research Council, Emergency Report No. 5 of The Industrial Health Research Board. Paper. Price, 3d. Pp. 16. London: His Majesty's Stationery Office, 1944.

This report confirms the opinion of previous investigation that reduction in hours of work affects hourly output favorably. However, great care must be exercised in interpreting results. Many additional factors must be considered, and of these technical improvements and reorganization of work are the most important elements leading to improved efficiency. The workers appreciate shorter hours, especially women with home responsibilities.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BASOPHILIC AGGREGATION TEST FOR LEAD EXPOSURE

To the Editor:—In one of our war plants about 12 employees were overcome by fumes from solder. Can you supply any information about the McCord test? M.D., Illinois.

ANSWER.—Preferably termed the basophilic aggregation test, the procedure mentioned finds its most useful application as a screening measure in the detection of lead absorption and lead poisoning suspects in group examinations. However, it may be used in individual examinations. Any one exposed to lead who presents the subsequently mentioned blood elements in excess of 1.5 to 2 per cent should be suspected as having lead absorption or lead poisoning. In the usual early lead poisoning the percentage ranges from 3 to 6 and exceptionally as high as 15. This test is not diagnostic. In the newborn, in various anemias, in early benzene poisoning, possibly in early arsenic poisoning and sometimes after extensive exposure to sunlight or to artificial ultraviolet light the test may be positive. In long standing lead poisoning and in the presence of lead sequelae the test will not be positive.

The basis of the test is the enumeration of all red blood cells containing basophilic material, that is, preformed stipple cells, reticulocytes and red cells containing diffuse basophilic substances seen as polychromatophilic cells as stained with a Romanovsky stain. The staining procedure seeks to obtain laking of the red cells but leaving behind, within the cell form, clumped basophilic material which is much more visible under the microscope than the diffuse basophilic material as seen in a polychromatophilic cell. The stain used is:

Sodium borate	1.0 Gm.
Methylene blue	2.0 Gm.
Distilled water (boiling).....	100 cc.

The sodium borate is dissolved in the boiling distilled water and to this is added the methylene blue. After filtering, this stain is ready for use and provides a stable, satisfactory and uniform stain for at least two weeks. If used for long periods, a progressive formation of precipitate may appear.

For reasons unknown, not all batches of this stain prove satisfactory. Experience has shown the necessity of working on a trial and error basis. Apparently, best results depend on a highly critical pu value, but this value has not been standardized.

In carrying out this test, one or more thin blood smears are made on the usual microscopic slide. After air drying, one half of the smear longitudinally is overlaid with a strip of filter paper, after which this is carefully wet with a small amount of methanol for fixation. This remains in place until dry. The remaining half is unfixed. Staining is then carried out, the staining time varying with different batches of stain and ranging from thirty seconds to ten minutes. Apparently, overstaining does not occur. After staining, the preparation is gently washed in distilled water in order not to remove the unfixed cells. After air drying, counting is carried out avoiding the boundary between the fixed and the unfixed portions. Customarily the total number of the stained cells in the fixed portion of the slide are counted in five high powered microscopic fields ($\times 4$). Then the basophilic aggregations showing up as fine or coarse skeins or as clumps of unnetted basophilic material are counted in twenty fields of the unfixed portion. The percental relationship between these total numbers is then established. In healthy adults the percentage of basophilic aggregations usually ranges from 0.3 to 1.3, less frequently to 1.5. In industry a team of three persons may make four hundred of these tests daily without difficulty. Reference:

McCord, C. P.; Holden, F. R., and Johnston. Jan: Basophilic Aggregation Test in the Lead Poisoning Epidemic of 1934-1935, *Am. J. Pub. Health* 25: 1089 (Oct.) 1935.

CANCER OF RECTUM

To the Editor:—Are statistics available as to the length of survival, without operation, of patients on whom an established diagnosis of primary carcinoma (adenocarcinoma or squamous) of the rectum has been made between the ages of 65 and 70? Captain, M. C., A. U. S.

ANSWER.—The average length of life in untreated rectal cancer (adenocarcinoma) is about seventeen months.

REFRACTORY ABSCESS OF THIGH

To the Editor:—A 2 year old child was recently seen with an abscessed cavity located in the upper and outer part of the left thigh. It was closed over when first seen, but the parents report that on at least four different occasions previously it had been incised and drained; in spite of packing and drainage, it never remained closed for more than a few days at a time. On curettement the cavity appeared to be entirely above the muscle sheath but extended to a depth of an inch and a half from the skin, passing somewhat medially across the anterior surface of the quadriceps. It drained well for a few days and has remained healed since. The pathologist's report on the scrapings obtained is as follows: "Gross description: several irregularly shaped pieces of yellowish, soft, fatty and connective tissue material, the largest piece about 1 cm. in its greatest measurement. Sections from a number of different places have essentially the same picture, with a lining composed of ill formed spherical masses of rather large cells grouped roughly as tubercles but with no giant cells. There is necrosis, in the center of which there are large numbers of polymorphonuclears and broken-up nuclear material. One partially formed giant cell is identified. Special stains for tubercle bacilli do not demonstrate any organisms. Careful search of the stained material reveals no fungi. Granulomatous inflammation of the soft tissues of the left thigh, probably tuberculous. Suggest probable origin in the bone or hip joint or extension of a psoas abscess. Please let me know the outcome of your further observations in this case." I had never seen this child before, since its parents had been living in California at the time of its birth and had returned to this locality only about six months before. They live on a farm, and the only close associates during the past six months have been the grandparents and two aunts, both of whom are young women less than 20 years of age. So far as the parents know, there was no contact with any case of tuberculosis while in California. Testing of the parents, a brother, the grandparents and the two aunts give negative reactions to the tuberculin test with purified protein derivative. The patient showed a definite reaction to the second strength of purified protein derivative. X-ray examination of the pelvis, lower spine and upper femurs shows no indication of bone disease. We are all somewhat puzzled as to a possible source of infection. Is there any further test that should be made? What treatment is advised? I have suggested ample rest, a nourishing diet and exercise not permitted to the point of extreme tiredness. Ray S. Wycoff, M.D., Lexington, Neb.

ANSWER.—The ordinary means of diagnosis have been well covered in this case, but the description of the scrapings certainly suggests tuberculosis. It is suggested that some of the material be sent to a laboratory for intraperitoneal injection into guinea pigs. The guinea pig is most susceptible to tubercle bacilli, and, while a negative result does not settle the question, a positive result would. The general suggestions for care are good; during the winter months cod liver oil would be a good thing for the child to have.

ASYMMETRICAL BLOOD PRESSURE—THERAPY WITH THIOCYANATES

To the Editor:—Is there any explanation for the blood pressure being about 30 points higher, both systolic and diastolic, in the morning after sleeping than before retiring? A woman aged 55 has had high blood pressure for several years, from 200/140 to 150/85 in the left arm. The left arm usually is 15 to 20 points lower than the right. The difference in evening and morning blood pressure applies to both arms. The patient is having considerable vertigo and headache. She is taking potassium thiocyanate. The blood level of this drug is being tested weekly. What is considered a safe level? Should the dose be varied in order to obtain this level? What is considered the level of danger? What symptoms indicate toxicity?

Edward F. Hemminger, M.D., Upper Darby, Pa.

ANSWER.—Asymmetry of the arterial tension in the two arms is not uncommon: Differences of 10 mm. of mercury or more in the systolic pressure and/or 5 mm. or more in the diastolic tension were observed in 15.7 per cent of a group of apparently healthy adults. Failure to realize that such asymmetry occurs frequently is undoubtedly due to the fact that the great majority of physicians fail to make observations on both arms. Recent studies have shown that the brachial systolic blood pressure is higher in the right than in the left in 70 per cent of normal persons and in 84 per cent of hypertensive patients. The degree of disparity increases with the degree of hypertension. The Amsterdams explain the frequent observation of lower tension in the left arm by pointing out that the anatomy of the aortic arch is such that the innominate artery, from which the right subclavian artery arises, is in direct line with the blood stream in its flow in the ascending aorta, whereas the left subclavian artery comes off the aorta at a greater angle. Thus many instances of differential tension may be essentially physiologic. Pathologic conditions associated with asymmetry of the blood pressure in the arms include cervical rib, aortitis, atrophy of an extremity such as that subsequent to injury, joint ankylosis or poliomyelitis, trophic disturbances such as may occur in tabes dorsalis, and localized arteriolar constriction.

It is unusual for the arterial tension to be higher immediately after rest and/or in the horizontal position. The observations of Gambill, Hines and Adson and of Sewell indicate that the pulse pressure tends to fall with a change from recumbency to an erect posture. The question does not state whether the morning observation was made with the patient recumbent or sitting erect. It is quite possible that the reflex rise in tension

which occurs with change in position from the horizontal to the vertical is exaggerated in the patient who has so obviously a variable spastic phase of hypertension. Gambill reports that his own arterial tension was almost uniformly higher in the morning than in the evening but offers no explanation of this phenomenon. It is characteristic for the arterial tension to fall considerably during sleep, and this fall is exaggerated in anxious apprehensive individuals. It is questionable whether the episodes of vertigo and cephalalgia described can be correlated with fluctuations of the arterial tension. Coincident anemia, which is common in hypertension, may decidedly aggravate such symptoms of cranial malcirculation.

The dose of potassium thiocyanate required to keep its concentration in the blood at a safe therapeutic level (5 to 10 mg. per hundred cubic centimeters) is extremely variable in different patients. Levels of 20 mg. or more are dangerously toxic. It must not be forgotten that the colorimetric method of Barker is none too accurate and that with levels around 15 mg. per hundred cubic centimeters of blood a toxic concentration may be approached. Though this drug is usually administered three times a day the blood concentration in most instances remains fairly constant throughout the day in patients receiving appropriate quantities. No correlation has been found to exist between the urinary output of thiocyanate and the daily intake or the blood concentration of the drug. The commoner symptoms of thiocyanate intoxication, in the usual order of their appearance, are muscular weakness, papular dermatitis, nausea, vomiting, mild fever, mental confusion and disorientation, aphasia, convulsions and coma. Thiocyanate is a safe vascular depressor substance only if used conservatively and with proper safeguards. The lowest blood concentration that yields satisfactory reduction of the arterial tension should be maintained. The margin between effective therapeutic levels and toxic levels is small. References:

REMOVAL OF SCABS

To the Editor:—What is the proper procedure in treating wounds that have been encrusted by scab formation? Some believe that the scabs of all wounds should be removed, while others maintain that if a scab is dry and solid with no serious accumulation underneath it should be left untouched until nature has completed healing underneath.

Gerhard W. Lorfeld, Captain, M. C., A. U. S.

ANSWER.—Careful review of the extensive recent literature on the subject of treatment of wounds contains no reply to this query. The reason for this is obvious: "A dry scab with no serious accumulation underneath" no longer presents a problem; removal of such a scab will result in formation of another scab. Any suspicion of the existence of infection underneath the scab calls for its removal.

None of the bulletins issued by the Army and the Navy on the subject of treatment of the wounds contain any reference to the query.

CALCULATION OF REFRACTION IN DISPLACED EYE

To the Editor:—I am unable to find definite information regarding the change in refraction in the eye produced by displacement of the lens. Can you tell me where I can determine the change in the refractive power of a normal eye produced by a displacement backward of the lens of 1 mm.?

Lyman A. Copps, M.D., Marshfield, Wis.

ANSWER.—If the lens is retroplacated 1 mm. so that the anterior surface lies 4.6 mm. behind the anterior surface of the cornea instead of 3.6 mm. (Gullstrand schematic eye), the eye will become hyperopic by more than 1 diopter. To determine the become hyperopic by more than 1 diopter. To determine the exact amount mathematically necessitates an entire recalculation for determination of the cardinal points. For guidance in such calculations the reader is referred to Duke-Elder's Textbook of Ophthalmology, volume 1, page 735, to A. C. Percival's The Prescribing of Spectacles, page 177, and to Tscherning's Physiologic Optics, page 29.

INSECTICIDAL AEROSOLS

To the Editor:—I understand that the gas freon is used to kill mosquitoes and was wondering if it had the ability to kill the insects that are found in houses and kennels, such as fleas, flies and moths. What amount should be used figuring on the cubic feet of a room or building? I should appreciate any information you can give me on this or any similar fumigation for moths and other insects.

Charles A. Manahan, M.D., Vinton, Iowa.

ANSWER.—The gas freon is not in itself used as an insecticide, but it is used as a carrier of insecticidal materials, such as pyrethrum extract and sesame oil in the aerosol method. Articles on this subject are as follows:

- Goodhue, Lyle D.: Insecticidal Aerosol Production: Spraying Solutions in Liquefied Gases, *Indust. & Engin. Chem.* 34: 1456 (Dec.) 1942.
Insecticides for the Army: The Aerosol Insecticide Program and Its Effects on the Insecticide Industry Now and After the War, *Sci.* 18: 91 (Nov.) 1942.
Goodhue, Lyle D.: Insecticidal Aerosols, in *Pests and Their Control*, vol. 11, No. 1, January 1943.

The first named article states that "an aerosol of pyrethrum extract and sesame oil produced by spraying a solution of these materials in dichlorodifluoromethane has shown considerable promise. This solution is prepared by dissolving 5 Gm. of a purified pyrethrum extract containing 20 per cent total pyrethrins and 2 Gm. of refined sesame oil per 93 Gm. of dichlorodifluoromethane. The solvent, which has a pressure near 90 pounds per square inch at room temperature, is an odorless, nontoxic, noninflammable gas, and the resulting aerosol may be used with safety in the presence of man and animals. Entomologists have tested this aerosol and find it very toxic to mosquitoes, especially yellow fever mosquitoes, *Aedes aegypti* (L.), which are killed in two minutes when as little as 5 m. of total pyrethrins and 10 mg. of sesame oil are suspended in 1,000 cubic feet of air. House flies and other species of flies frequently found around livestock barns are easily controlled."

The aerosols containing pyrethrum extract are at present required by the armed forces, particularly for use against mosquitoes, and are not available for civilian use.

For information on moth control, U. S. Department of Agriculture Leaflet No. 145, entitled "Clothes Moths," should be consulted.

DISCOLORATION OF SKIN FROM PERMANGANATE BATHS

To the Editor:—Kindly advise whether twice daily bathing in solutions of potassium permanganate (125 grains to each bathful of water) for even a month could result in a generalized dermatitis with bronzing of the whole body and darkening of the sclera and of the skin of the face. The patient is a man.

Aaron N. Gorelik, M.D., Bronx, N. Y.

ANSWER.—Such bathing could and ordinarily does produce a discoloration of the skin. A dermatitis could also be induced if the concentration of potassium permanganate was sufficiently strong to prove irritating. The darkening of the sclera doubtless would be produced in the same way as the discoloration of the skin. It is not likely that the permanganate would be absorbed through the skin and then carried to the sclera systemically; this chemical is so unstable as to preclude its carriage through all the organic material of the blood without being reduced.

RESISTANT PINWORM INFECTION

To the Editor:—For the past fourteen months the wife of an army officer has been under treatment at various stations for recurrent attacks of *Oxyuris vermicularis* infections. Therapy has followed the usual line such as various types of enemas, the use of enteric coated gentian violet tablets and the like. For the past four months these measures have been repeated with no degree of success. Hygienic measures have been adhered to rigidly. At no time has the stool examination revealed the presence of ova of *Ascaris lumbricoides*. The question has now been presented to this effect: Will removal of the appendix in its role as a possible harbor of refuge for the pinworms offer any degree of success in ultimate cure of this condition? Vaginal examination has not been done on this patient.

Captain, M. C., A. U. S.

ANSWER.—Assuming the several diagnoses to have been based on specific identification of the eggs or individual pinworms, it appears somewhat improbable that periodic recurrences of infection after adequate approved treatment were likely to arise without reinfection. Resort to surgery in the absence of recognizable signs or symptoms pointing to the appendix seems to be unjustified at least before a most careful critical investigation into the personal habits and hygiene of the patient and the associated human environment. Such procedure, in view of the ready autoinoculability and self-limited character of pinworm infection without reinfection, with persistent use when indicated of such anthelmintics as gentian violet, offers more promise of ultimate success in treatment than resort to removal of the appendix on a chance that egg producing female worms may be temporarily lodged there.

THE USE OF INSULIN AND THE ABUSE OF GLUCOSE

IN THE TREATMENT OF DIABETIC COMA

HOWARD F. ROOT, M.D.
BOSTON

Deficiency of insulin is the cause of diabetic coma. Anew this has been demonstrated by the discovery of experimental alloxan diabetes,¹ in which diabetic ketosis and coma result when the islands of Langerhans which secrete insulin are destroyed. Here is a new method for the production of diabetic coma in its pure and uncomplicated form. Insulin cures coma because it enables the body to utilize glucose present in the blood and fluids of the tissues. It restores glycogen depots and provides energy for the body by oxidation of carbohydrate instead of fat and so stops excessive ketone production. If one would only appreciate this action of insulin, the administration of excessive glucose intravenously and by mouth with its lethal effect in patients with severe diabetic coma would be ended and more recoveries reported. My associates and I are so impressed by the reported high mortalities in diabetic coma published by those who treat it with glucose as compared with our recent series of 123 successive cases between Oct. 21, 1940 and May 1, 1944 with but 2 deaths treated without glucose that when we hear of a diabetic coma death our first question is "Did the patient receive glucose?"

In this paper I wish to present new observations and refer only briefly to such data from the series of 601 coma cases that ended May 1, 1944 as have not been given in previous reports.²

DECLINE IN MORTALITY

We naturally take pride in the fact that but 2 deaths in coma have occurred in the last 123 consecutive cases observed up to May 1, 1944, a percentage of 1.6 in contrast to 12 per cent for the 478 earlier cases (table 1). We attribute our low mortality to the more rapid administration of insulin in larger doses in the first three hours after admission to the hospital. The steady increase in dosage from 83 units to an average of 216 units during the first three hours of treatment has been due to a recognition of two facts: (1) the value

of insulin is greatest early in treatment, and (2) complications formerly regarded as lethal may be more successfully treated if coma is rapidly controlled. The maximum dose given in twenty-four hours was 1,410 units, but the average doses in twenty-four hours were 237 and 287 units for the two series. It is the insulin given in the first hours of treatment which counts most heavily.

TWO COMA DEATHS WITH AUTOPSY

A girl aged 19 years (patient 43) was transferred from another hospital on April 10, 1943 in coma of thirty hours' duration complicated by sinusitis. On arrival she was profoundly unconscious with soft eyeballs, anuric, the blood sugar was 534 mg., blood carbon dioxide 11 volumes per cent and the rectal temperature 101.4 F. With intravenous fluid and insulin, 200 units, the blood sugar fell to 190 mg. Death occurred five hours after entry. A complete postmortem examination was obtained, including the brain. The anatomic and microscopic diagnoses were purulent sinusitis, sphenoid and ethmoid; early bronchopneumonia, right; atherosclerosis of aorta; simple cysts of ovary, right; remote appendectomy. The immediate cause of death was sepsis due to infection with hemolytic *Staphylococcus aureus*.

A youth aged 19 years (patient 52) in coma of twenty-two hours' duration had received 400 Gm. of glucose in another hospital during the first twelve hours of treatment for undoubted coma. Then because of his downward progress insulin, inadequate in amount, was employed. On admission to the Deaconess Hospital the blood sugar was 680 mg., blood carbon dioxide 23 volumes per cent, nonprotein nitrogen 73 mg. He received 320 units of crystalline insulin. Death occurred in nine hours. Autopsy was negative. Death was due to delayed and inadequate use of insulin. (This is the exceptional case referred to in table 1.)

ACETONE BODIES IN THE BLOOD

An abnormal concentration of acetone bodies in the blood is an essential feature of diabetic coma. It is usually proportional to the severity of coma and the amount of treatment required for recovery; this is especially so if due allowance is made for the fact that the susceptibility of the brain to acidosis will be affected by the age of the patient, by the duration of the diabetes, by the presence or absence of acute infection and especially by such other factors as coexisting arteriosclerosis and nephritic lesions. In table 2 are listed determinations of total acetone bodies in the whole blood in a series of 31 cases of diabetic coma in which the blood carbon dioxide content was 20 volumes or less and 10 cases of ketosis in which the blood carbon dioxide content had not reached the coma level of 20 volumes per cent. The determination gives the total amount of acetone, diacetic acid and beta-oxybutyric acid in the whole blood expressed as milligrams of acetone per hundred cubic centimeters of blood. This series is arranged with the highest values for blood acetone bodies first and in the descending order. By unconsciousness is meant a state in which the patient is

completely unresponsive to even painful stimulants and does not resist such measures as the passing of the stomach tube. Patients listed as drowsy would respond to questions, but in most instances after recovery they would not remember the passing of the stomach tube or any other incidents for a period of a day or two during acidosis; that is, cerebral function was very seriously affected. Patients who were conscious did have dyspnea but were quite able to cooperate.

The state of unconsciousness did not occur with acetone values under 100 mg. with a single exception. A girl aged 19 years (patient 43) arrived unconscious and anuric. Her death was due to a purulent involvement of the sinuses with obstruction of the nasal passages. The low concentration of acetone bodies is consistent with the disappearance of acetone bodies in the urine during the last few hours of life in severe acidosis and is in some way related to the terminal cachexia of diabetes and severe infection. In a series of 21 patients with blood acetone values of over 100 mg., 10 were female, 11 male. Only 2 were over the age of 40 years. A patient aged 72 years had an adenoma of the thyroid with hyperthyroidism; another patient aged 60 had diabetes for twenty years. It was these two older patients who were unconscious with blood acetone values of 104 and 125 mg. The duration of diabetes varied from two years to nine years. The highest blood sugar values and the highest insulin doses were required in the groups with the highest blood acetone values. The average blood sugar for the patients with blood acetone values above 140 mg. were 748 mg. Insulin requirement for the first twenty-four hours for this group of patients was 553 units, but 1 patient received only 126 units. The effect of impaired renal function in bringing about retention of acetone bodies is shown by a woman aged 76 years who entered with gangrene and auricular fibrillation. The blood acetone value was 133 mg., yet the blood carbon dioxide content was 38 volumes per cent. The nonprotein nitrogen was 61 mg., yet she made a good recovery after thigh amputation.

The rapidity with which the concentration of total acetone bodies in the venous blood of patients declines under treatment for diabetic coma deserves further

sugar was 70 mg., a result accomplished with 214 units of insulin. This is the typical change in blood acetone bodies, provided sufficient insulin is given to check excessive ketone production by the substitution of carbohydrate for fat in the metabolic mixture, probably

in part through restoration of more nearly normal hepatic glycogen.

Ketone bodies are normally present in the blood in exceedingly small amounts and are now regarded as normal metabolites. They may be formed from certain of the amino acids (ketolytic amino acids, tyrosine, leucine, isoleucine and phenylalanine) and from fatty acids. It was formerly thought that their production was due solely to the absence of oxidation of carbohydrate. Now carbohydrate oxidation is regarded as antiketogenic; in the absence of carbohydrate more fat is used, with a consequent abnormal increase in the production of these acetone bodies.² In an artificially produced ketonemia developing during a fasting cure in 1 case described by Brugel³ the blood acetone value rose to 19-20 mg. for several days, during which time the patient felt perfectly well. Barach⁴ described ketonuria in Marathon runners. The striking difference between the effects of fasting in diabetic patients and in three obese nondiabetic subjects is demonstrated by Dick, Goldner and Singer.⁵ The data obtained were compatible with Stadie's theory of a utilization limit for

		1947-1944 216

* Only cases showing blood carbon dioxide values of 20 volumes per cent (8 cc. millimoles) or less are included with the exception of case 52.

study. In this series the fall in acetone body concentration roughly parallels that in the blood sugar. A youth (No. 5, table 2) entered in coma with a blood sugar of 540 mg., a carbon dioxide of 15 volumes per cent and total acetone bodies of 162 mg. In three hours the blood acetone level fell to 112 mg., while the blood sugar fell to 320 mg., and at the end of twenty-four hours the blood acetone level was 9 mg. and the blood

fat and a threshold for ketosis. According to Stadie the level below which fat metabolism is complete is about 2.5 Gm. per kilogram body weight daily.

It is a lack of insulin which is essential for the production of diabetic coma. It is easy to produce ketonemia in nondiabetic patients on starvation or on fat diets without carbohydrate, but no serious condition remotely resembling diabetic coma ever occurs in a normal animal or normal human being who has a normal supply of insulin, no matter what method is employed to increase the concentration of ketone bodies in the blood and urine.

As a means of estimating the critical character of diabetic coma the determination of the carbon dioxide content of venous blood continues to be in our experience the most valuable single analysis. The measurement of acetone bodies in the urine is deceptive because of failing renal function. The content of acetone bodies in the blood, while important, is not so reliable as the blood carbon dioxide in determining the degree of depletion of the alkali reserve and the imminence of lethal irreversible changes in the central nervous system.

CHANGES IN THE TOTAL BASE OF THE BLOOD AND SHOCK IN DIABETIC COMA

In table 3 determinations of total base in the venous blood in 10 cases of diabetic coma are shown with the accompanying values for total acetone bodies, carbon dioxide content, sugar and serum protein. In comparison with the normal value of 155 milliequivalents per liter, every case with 1 exception shows a reduction in total base to levels varying from 135 to 146.8 milliequivalents. The blood specimen used for base determination of patient 51, a man aged 24, was drawn after he had received 4,000 cc. of isotonic solution of sodium chloride intravenously. This patient, together with patient 50, a youth aged 16 years, whose total base rose from 146.8 to 154.8 milliequivalents in two hours and forty minutes, indicate how rapidly restoration of blood base and disappearance of shock may occur if sufficient amounts of isotonic solution of sodium chloride are given during the first two hours of treatment.

The reduction in carbon dioxide content of the blood to values varying from 7 to 18 volumes per cent depends on the accumulation of ketones in the blood. In this series the values for total acetone bodies expressed as acetone varied from 60 to 195 mg. per hundred cubic centimeters. Dehydration is an important factor, but in this series of 10 patients only 3 show values for serum protein exceeding 8.0 per cent. These 3 cases (47, 45

and 50) had extreme ketosis, as shown by blood acetone values of 120, 144 and 195 mg. per hundred cubic centimeters, yet all recovered.

It is unfortunate that the changes within tissue cells, which necessarily depend on the surrounding extracellular fluid, are not accessible to chemical study. The diagrams of Guest⁷ and Rapoport, reproduced by

Gamble,⁸ show the typical changes in the red blood cells during diabetic coma and recovery. A large reduction in base is consequent on the fall in base concentration in the plasma, that is, a reduction in sodium of the plasma brings about removal of potassium from the cells. This withdrawal of intracellular base in diabetic acidosis was shown by the increase in excretion of potassium in the urine described by Atchley and Loeb.⁹ Increases in hydrogen ion concentration, changes in inorganic phosphate and diffusion of chloride ions into the cells illustrate a group of structural changes important in other tissue cells as well as the red corpuscles.

The acute shock associated with burns or trauma has been shown by Rosenthal¹⁰ in experimental studies to be relieved by sodium chloride solution given by mouth or by vein with higher rates of recovery than when plasma is given intravenously. Serum was slightly more effective when given orally than when given intravenously. The effect of serum was due to its electrolyte content rather than to its protein content. Dextrose solution was without effect. Apparently the sodium ion is of such specific importance that the state of shock may be regarded as due to tissue damage resulting from sodium deficiency. Clinical confirmation is afforded by the work of Fox,¹¹ using sodium lactate solutions given by mouth. These results again support the practice of giving isotonic solution of sodium chloride subcutaneously and by vein to coma patients in shock up to 10 or 15 per cent of body weight. Smaller amounts may be ineffective.

Treatment aimed at the heart is without value in our experience in uncomplicated diabetic coma, no matter what the blood pressure or pulse rate may be. The pulseless and anuric stage of the patient is due to dehydration and shock associated with the loss of water and electrolytes, of which sodium chloride is the most important.

SUPPLIES OF CARBOHYDRATE IN BODY TISSUES IN COMA

In table 4 are shown the approximate differences in carbohydrate content of the main tissues of a normal man and a man in diabetic coma, each weighing 70 Kg.

In Cunningham's Anatomy, seventh edition, it is stated that 42 per cent of a man's weight is muscle. In 30 Kg. of normal muscle 180 Gm. of glycogen would be present, in contrast to 90 Gm. in the muscles during diabetic coma.

In diabetic coma Geelmuyden¹² found that the glycogen content of the liver varied from 0.96 to 3.03 per cent while the fat varied from 2.63 to 7.32 per cent. Bloor¹³ points out that a reduction in the glycogen content of the liver is apt to be associated with an increase in fat content. The relationship is by no means consistent. Therefore, if the normal liver contains 108 Gm. of glycogen, in diabetic coma liver glycogen may be reduced to 18 Gm.

When the level of the blood sugar is raised to high levels the skin appears to be one tissue in which the excess sugar enters in large concentration, playing a role similar to the fields along the course of a river, which are flooded when the stream rises too high. Trimble and Carey¹⁴ analyzed the skin and muscles of diabetic patients at the Deaconess Hospital and showed that similar concentrations of sugar in the skin followed changes in the sugar of the blood. An increase in the sugar of the muscles did occur, but it was not as great as the increase of sugar in the skin. In the diabetic patients, when the blood sugar varied in 5 patients from 213 to 345, the sugar in the skin varied from 177 to 222 mg. per hundred cubic centimeters in contrast with the average value of skin sugar in non-diabetic patients of 56 mg. As determined by Bischoff,¹⁵ in one young woman and in one young man the weight of the integument amounted to 3.18 and 4.85 Kg. Assuming the concentration of glucose in the skin of a man weighing 70 Kg. with a blood sugar of 700 mg. would be roughly four fifths the concentration of the sugar in the blood, about 28 Gm. of glucose would be present in the skin, as against 4 Gm. in the normal skin.

Extracellular fluid including the blood plasma amounts to 30 per cent of body weight. The concentration of glucose in the extracellular fluid varies somewhat but in general parallels that of the blood. Venous blood sugar is stated as 80 mg. per hundred cubic centimeters, but it is known that arterial blood sugar is oftentimes higher by 5 to 20 or more milligrams per hundred cubic centimeters. It is true, that the intracellular and cerebrospinal fluids contain glucose in somewhat lower concentration than the venous blood. It seems likely that with the great increase in the concentration of glucose in the extracellular fluid some increase in intracellular glucose must occur. Otherwise, harmful effects on the cell membrane might result. Another possibility in coma with excessive hyperglycemia is the occurrence of a high level within muscle or liver cells of glucose compounds or derivatives easily converted into glycogen by the action of insulin. In that case the amount of carbohydrate in the tissues in coma may well be equal to or even greater than that of the normal individual of equal weight.

The problem in treating diabetic coma is actually the problem of converting by the use of insulin a large amount of unused and unusable glucose present in the tissues of the body into glycogen and energy. The administration of glucose does not increase the oxidation

of carbohydrate during coma (Root and Carpenter¹⁶). A sufficient supply of glucose is present in body fluids to make possible glycogen formation during the six to eight hours which may necessarily precede the resumption of the diabetic diet. In twenty-four hours of bed rest the caloric requirement of 1,500 calories may be satisfied by protein 70-75 Gm., fat 65-75 Gm. and carbohydrate 100-150 Gm.

LESSONS FROM CASES REPORTED BY OTHER PHYSICIANS

Requests within a year for advice, consultation or review of 14 cases of diabetic coma with fatal outcome brought us into contact with the results obtained when patients in diabetic coma have received glucose solution in large amounts intravenously or subcutaneously. The following cases are typical of the 14:

CASE 1.—A boy aged 12 years, admitted in coma with a blood sugar of 475 mg., received intravenously 1,000 cc. of 5 per cent glucose and 50 units of insulin at 4 p. m. From 6 till 10 p. m. he was given six injections of 50 units of insulin at intervals. From 11 p. m. till 6 a. m. he was given fourteen injections of 30 units at thirty minute intervals. During this same period he received 1,000 cc. of 10 per cent glucose solution intravenously and two intravenous infusions of Hartmann's lactate solution. Karo syrup was given by stomach tube until the child had received a total of 300 Gm. of glucose (including 150 Gm. as glucose solution by vein). His fluid intake was 5,675 cc. The urine never became sugar free; acetone never disappeared from the urine in spite of the fact that he received 770 units of insulin. He died at the end of eighteen hours. Autopsy was negative. If the patient had been given no glucose intravenously or as Karo syrup by mouth but had received a moderate dose of perhaps 150 to 200 units of insulin immediately on admission, the result would have been a fall in blood sugar due to storage of the excess glucose as glycogen and the oxidation of sufficient quantity to replace and thus to reduce the excessive ketone formation from fat, with probable recovery.

CASE 2.—A girl aged 15 years entered another hospital in diabetic coma. The blood sugar was 400 mg. On admission, 600 cc. of urine was catheterized. One hour later another 400 cc. of urine was obtained. She was given 1,500 cc. of 5 per cent glucose solution not long after admission, and this was repeated three hours later. Anuria came on about one hour after admission and no urine was secreted during the remainder of her hospital stay. At the end of twelve hours the blood sugar was 667 mg. and the carbon dioxide combining power was 11 volumes per cent. At this time an attempt was being made to provoke urine secretion by the intravenous administration of 50 per cent glucose solution. This attempt naturally failed, and the child died at the end of eighteen hours with anuria. Autopsy was negative.

When coma is rapidly advancing, the administration of glucose solution intravenously does not produce diuresis and is often sufficient to tip the patient over into the stage of exhaustion and anuria, with fatal results.

HARMFULNESS OF GLUCOSE ADMINISTRATION IN DIABETIC ACIDOSIS

In the cases reported by Root and Carpenter, glucose solution given intravenously did not bring about any rise in respiratory quotient indicating any increase in glucose oxidation. When insulin is given in diabetic coma, the respiratory quotient will rise because some of the excess glucose present in the blood and tissue fluids is oxidized and some converted into glycogen. Administration of 50 or more grams of glucose in coma, as commonly practiced, is harmful because (1) no more than 5 to 10 Gm. of carbohydrate can be or need be oxidized per hour in order to check ketone formation. glucose neutralizes the action of insulin. (3) a rise in blood sugar is produced which makes it difficult to determine the required insulin dosage. (4) such excessive hyperglycemia is harmful to the pancreas. (5) excessive glucose concentration in the blood and tissues under the condition of acidosis will result in anuria and (6) the experiments of Astwood, Flynn and Krayer¹⁷ show that excessive glucose damages the liver.

DIAGNOSIS AND TREATMENT OF DIABETIC COMA

1. *Diagnosis.*—Patients suspected of having diabetic coma belong in the hospital. Diagnosis is often difficult, especially if the degree of acidosis and coma do not correspond. In table 5 a brief summary of the clinical and chemical features of 5 recent cases is given.

2. *Preparation Prior to Hospital Admission.*—Transfer of the patient should be carried out early rather than late as an emergency measure. The hospital should be one in which laboratory service is available day and night, including holidays and Sundays. At the Deaconess Hospital a wartime diabetic coma emergency service has been organized through the cooperation of the staff and the hospital authorities. The objects of this wartime diabetic coma service are to (1) keep available a bed for a coma case, (2) provide special diabetic nurses, (3) guarantee laboratory analyses of the blood and

TABLE 5.—*Differential Diagnosis in Comatose Patients*

	Unconscious	Respiration	Blood Sugar	Blood Acetone Bodies, Mg.	Pulse	Blood CO ₂ , Vol%

urine at any time and (4) offer consultative service to any doctor in the vicinity who has a coma case.

3. *Insulin.*—When it is learned by phone that a patient is to be brought to the hospital, a preliminary dose of 20-60 units of insulin is given by the home physician or by the family, provided the diagnosis seems probable. At the hospital the following preparations are made: The bed is made ready with blankets and hot water bottles, and apparatus is assembled for the giving of salt solution subcutaneously and intravenously and for the carrying out of gastric lavage and giving of an enema. On arrival the patient is put in bed well covered with a blanket and surrounded by hot water bottles placed outside the blanket, so that burns of the skin will not occur. A blood specimen and urine specimen are immediately obtained for analyses for blood sugar, carbon dioxide, nonprotein nitrogen and blood chloride. An extra box is kept on hand so that venous bloods can be withdrawn and kept under oil.

The immediate problem concerns the amount of insulin to be given in the first two hours. Two facts make the decision difficult: (a) resistance to insulin increases rapidly as acidosis advances and (b) the law of diminishing returns applies to the efficiency of insulin, so that the expected result from the second and succeed-

ing 50 units may be obtained only by greatly increasing the dose. A striking relation exists between the level of blood sugar and the total amount of insulin required in the first twenty-four hours of treatment to bring about improvement. In table 6 it is seen that in 2 adults whose blood sugars were 1,380 and 1,540 mg. the

TABLE 6.—*Blood Sugar Level Correlated with Insulin Dose in 123 Coma Cases*

Blood Sugar Level on Admission, Mg. per 100 Cc.	Number	Average Insulin Requirement During First 24 Hours
1,500-1,600	2	1,224
1,000-1,300	15	815
600-1,000	26	387
400-600	9	230
200-400	51	162

average insulin requirement in the first twenty-four hours was 1,224 units. The decline in insulin requirement parallels the blood sugar level. Indeed, in 51 cases out of the 123 cases in which the blood sugar level was between 200 and 400 mg. the average insulin requirement was only 162 units. It should be noted that, among patients whose blood sugar levels were less than 400 mg. on admission, in many instances some insulin had been given prior to admission by telephone order. All other measures, such as provision of warmth, fluid and salt intake, have an important place, but no question is so important as the decision regarding the total number of units of crystalline insulin to be given in the first hour of treatment. Many a patient in diabetic coma receives plenty of insulin but, owing to delays or indecision in the first two or three hours, too little insulin is given at the time when it will count the most. Insulin given six hours after admission in an unconscious patient is probably worth unit per unit less than one-third what it is worth during the first hour after admission. The average adult, drowsy and with a blood pressure over 100 mm., would receive 50 to 100 units. A child with diabetes recently discovered might need 20 to 40 units as an initial dose. However, in patients profoundly unconscious, in shock and dehydrated usually 100 units should be given subcutaneously and 50 or more units given intravenously. A second dose would probably be given one-half hour later. By the end of an hour some of the laboratory reports will be available, and with blood sugar values more than 600 mg., especially if the patient is in shock and is a patient with diabetes of long duration, we would usually expect 200 to 300 units to be administered in the first hour. The fundamental principle in the use of insulin is to give enough insulin to obtain the pharmacologic effect; namely, utilization of the excess glucose present

TABLE 7.—*Schedule for Administration of Insulin*

Benedict reaction Insulin (units required)	Red	Orange	Yellow	Yellow-Green	Green	Blue
	24	20	16	8	0	0

in body fluid, deposition of glycogen and cessation of excessive ketone formation. The most reliable evidence that this change in metabolism has taken place is the decline in blood sugar level. Urine and blood tests should be done at least once in two hours, and the insulin dosage may be planned in the average case in which an adequate dose has been received during the first few hours of treatment, in accordance with the schedule presented in table 7. As the patient's condi-

17. Astwood, F. B.; Flynn, J. M., and Krayer, O.: Effect of Continuous Intravenous Infusion of Glucose in Normal Dogs, *J. Clin. Investigation* 21: 621, 1942.

tion improves, the interval for the collection of specimens and giving of insulin may be increased to three, four or six hours. During this period the clinical condition of the patient, including particularly the mental state, type of breathing and the pulse, will help in deciding the plan of administration of insulin. However, no plan of treatment based on mathematical calculations of the blood sugar and carbon dioxide will take the place of constant bedside observation of the patient and adjustment of treatment to that patient's changing condition.

4. *Fluids and Salts*.—Dehydration, hemoconcentration, falling blood pressure and reduced peripheral blood flow with consequent cold, purplish extremities, dryness of the skin and softness of the eyeballs are the distinguishing features of severe diabetic coma. This shock syndrome seems to depend chiefly on the loss of sodium and water consequent on insulin deficiency and acidosis. Sunderman¹⁸ found that administration of insulin to the diabetic human being causes transfer of water and electrolytes from the serum into the tissues. Therefore in treating diabetic acidosis the administration of hot broths and saline solution early in acidosis and in liberal amount is of fundamental importance but not sufficient without insulin. Ordinarily, to unconscious patients with low blood pressure we would give simultaneously 1,500 cc. of salt solution intravenously and 1,500 cc. subcutaneously within a few minutes after admission into the hospital. This may need to be repeated one or more times within the next few hours of treatment. In patients with anuria a safe rule is to leave the needle in the vein of the arm or the ankle and let salt solution flow continuously 1 liter per hour until blood pressure rises and urinary secretion begins, provided it has been shown that the anuria is due to the ketosis and shock and not to some complication. Actually, in 2 cases reported by Root and Riseman¹⁹ anuria was relieved only when 13,800 cc. and 11,600 cc. of salt solution were given parenterally during the first twenty-nine hours of treatment. Fifty cc. of 10 per cent salt solution may be given intravenously when anuria is accompanied by a reduction in plasma chloride. The average patient will need from 4 to 7 liters of fluid within the first twenty-four hours. Enemas, not only once but repeatedly, may be necessary. The giving of fluid by mouth is limited to 100 cc. per hour only after the stomach has been washed out.

5. *Transfusion with Whole Blood or Plasma*.—Actually there has been no loss of blood protein or plasma in diabetic coma. Hemoconcentration is due to dehydration. The effective agents in diabetic coma, namely insulin, water and salt, are effective because they replace definite deficiencies. Actually there seems to be no good practical or theoretical reason for believing that plasma or whole blood is needed or can very often be of use in the uncomplicated case of diabetic coma.

6. *Gastric Lavage*.—Rarely should a patient in true diabetic coma be treated without drainage of the stomach and lavage with warm water within the first hour after admission. Usually the stomach is dilated and distended with a large amount of fluid containing food remains that are colored black because of bleeding from the stretched gastric mucosa. A pulse rate of 240 has been known to fall to 150 within fifteen minutes after a

distended stomach was washed out. A large Ewald tube is usually more effective than a small duodenal tube.

7. *Enemas*.—A cleansing enema should be given and in severe cases repeated during the first few hours of treatment.

8. *Food*.—It is our plan to begin the administration of food within four to six hours after admission, provided the patient has no complication which would prevent it, and provided sufficient insulin has been given promptly to have brought about clinical improvement. The administration of food is given hourly, 3 to 4 ounces, including warm broth, salted liquid and thin gruel or tea with a little sugar. Some patients will take a similar amount of orange juice or ginger ale. Carbohydrate 10 Gm. per hour and a total of 30 to 50 Gm. each of protein and fat usually are the upper limits during the first twenty-four to thirty-six hours. The use of intravenous dextrose solution during the first hours of treatment is contraindicated. After a sufficient amount of insulin has been given, if the patient cannot be fed by mouth, then from six to twelve hours later intravenous injection of glucose solution can be used as a means of providing food.

9. *Alkalis*.—No justification for the use of alkali is found in the record of our last 123 cases, in which only two deaths occurred. If alkalis have been used, the blood carbon dioxide value may be dangerously misleading. It is extremely important to remember that the patient in diabetic coma may still die of coma even though the carbon dioxide of the blood is raised to normal by the administration of alkalis.

10. *Stimulants*.—Patients unconscious for several hours with evidences of peripheral circulatory failure, low blood pressure, rapid weak pulse and cold mottled extremities may be given, in addition to the treatment already recommended, caffeine, epinephrine, ephedrine or transfusion. The benefits observed seem to be temporary and slight.

11. *Prevention of Diabetic Coma*.—As with some other diseases, methods aimed at the prevention of coma may accomplish more than its treatment. A patient should be taught practical and simple methods for prevention, and particularly what actions should be taken in the early stages. A patient must know how to test the urine and must realize that frequent testing of the urine at home at daily intervals should result in prompt action and medical advice when the tests show that the diabetes is not under proper control. He must know how to give his insulin dose accurately and well. He must know how to weigh and measure food and substitute one food for another. A series of simple rules should be taught to all diabetic patients no matter how mild their condition seems in its early stage. They should be in close contact with their physician in order that at intervals more careful estimates of the diabetic control may be made and in order that patients may have the advantage of new features of treatment.

SUMMARY

1. In a series of 478 cases of coma observed from May 1923 to August 1940 the mortality was 12 per cent. When the insulin given in the first three hours of treatment was increased from 83 units in 1923-1927 to an average of 216 units among 123 consecutive cases treated between August 1940 and May 1, 1944 the mortality was only 1.6 per cent.

2. Diabetic coma is an emergency due to acute insulin deficiency requiring administration of adequate, often large doses of insulin in the first three hours.

18. Sunderman, F. W.: The Water and Electrolyte Distribution in Diabetes Mellitus, *Am. J. M. Sc.* 205: 102, 1943.
19. Root, H. F., and Riseman, J. E. F.: Exceptional Requirement of Insulin and Salt Solution in Diabetic Coma, *J. A. M. A.* 110: 1730 (Mar. 21) 1936.

3. Estimation of the insulin requirement is difficult because (a) insulin resistance increases hourly with acidosis and (b) the law of diminishing returns applies to insulin.

4. Treatment should be carried out in a hospital.

5. Important aids in treatment are (a) use of isotonic solution of sodium chloride intravenously or subcutaneously administered, 4,000 cc., or, when necessary to overcome shock and impending anuria, up to 10 per cent or even 15 per cent of body weight, and (b) gastric lavage.

6. The harmful effect of glucose administration may be concealed in early diabetic coma by the insulin simultaneously administered; the moderate case of coma may be converted into a severe one requiring excessive insulin dosage. In advanced coma glucose administration either by mouth or by needle may cause anuria and death.

81 Bay State Road.

ABSTRACT OF DISCUSSION

DR. EDWARD S. DILLON, Philadelphia: Dr. Root has considered briefly most of the important therapeutic agents used in the treatment of diabetic acidosis. Of these, much the most important is insulin. He has emphasized the giving of large doses early, and with this I am in entire accord. The attending physician by the end of four hours can approximate from the chemical examinations of the blood and the clinical condition of the patient what the total insulin requirements are and realize that most of the insulin should be given within four hours and not strung out in small doses for many hours. During the first five months of this year, 15 patients with diabetic acidosis have been admitted to my service at the Philadelphia General Hospital, all of whom recovered. The average amount of insulin given was 251 units, of which 183 units was given within the first four hours. The average blood sugar on admission was 596 and the average carbon dioxide 14. The average carbon dioxide at ten and one-half hours was 51. The second important matter which Dr. Root has considered is the use of glucose. When the blood sugar on admission is above 400 there is plenty of glucose present for a vigorous carbohydrate combustion if adequate insulin is given, and there is no need of giving glucose during the early hours of treatment. The giving of glucose early seriously interferes with estimating the total insulin requirement, as all blood sugar determinations, except the one on admission, are unpredictably influenced by the glucose. However, we do use glucose, introduced by a nasal tube, in the early hours if the admission blood sugar is below 400, or in later hours if the blood sugar is falling rapidly, in order to keep out of hypoglycemia. All patients with diabetic acidosis are dehydrated. There has been severe loss of sodium and also chloride. These losses must be made up by the administration of isotonic solution of sodium chloride. Our patients usually received 1,500 to 3,000 cc. subcutaneously. I should not recommend the large amounts of isotonic solution of sodium chloride intravenously which have been suggested by Dr. Root. Large amounts of saline solution in the circulation may precipitate the syndrome of shock, not cure it. The plasma proteins are usually of normal concentration, but the total blood volume is reduced, and the total proteins are reduced. Saline solution reduces the plasma protein concentration, and the blood volume cannot be maintained. Something must be given which will stay in the circulation and maintain blood volume, and the obvious answer is plasma.

DR. ROLLIN T. WOODYATT, Chicago: I agree with Dr. Root that the prime essential in the treatment of a patient with diabetic coma is to give a decisive dose of insulin. If you do that, it really does not make too much difference what else you do. In my own clinic we manage by six hour periods. If we have a patient showing definite symptoms of acid intoxication we start with what we think will be an adequate dose. A patient weighing 60 Kg. will be given 60 to 120 units at

once. This will be repeated three hours later and again at the end of the period. Dr. Root has suggested that once in a while you may run into a patient with insulin resistance and that it might be well to double those doses against such a contingency, which I think is a point well taken. Certainly it would do no harm. In the first six hours of management of a patient with serious symptoms of acid intoxication there is no possibility of an insulin reaction. In the second period, if the patient was not deeply in when he entered, there would be a possibility, but as long as you keep sugar running through into the urine you cannot have an insulin reaction, and if in the second period the respiration has come down, the nausea has cleared and the ferric chloride reaction in the urine has become negative, you can then give 50 to 100 Gm. of orange juice or an equivalent at one hour intervals and gradually come down from period to period with the insulin dose. But as long as glycosuria and ketosis are still present the maximum doses should be sustained. I cannot too strongly endorse what has been said by the other two speakers as to the fallacy of administering glucose in the early periods of management when ketosis is present and the body is already overloaded with sugar. There never was any sound theoretical basis for that procedure. It is no new idea and there has never been any sound clinical support for it. Second in importance to the giving of adequate doses of insulin and keeping them up steadily until the patient is out of the woods is the restoration of the water balance. In our own experiments with intravenous injections of glucose and salt to produce artificial dehydration we have found that between normal hydration and extreme dehydration there may be a difference of 5 per cent or less in the body weight. And it is not necessary to restore all of the water that has been lost to annul the symptoms of clinical dehydration. It is our practice to give patients of average weight a liter of water, usually in the form of isotonic solution of sodium chloride each six hour period for the first twenty-four hours, and when that is done the tongue will be moist, the urine will be copious and the thirst allayed in the first twelve hours, as a general rule. I concur with the second speaker that 7 or 8 liters of fluid in a diabetic coma case is abnormal, unnecessary and undesirable. The giving of such quantities in general practice must lead to edemas, and it is capable of causing circulatory failure.

DR. SAMUEL SOSKIN, Chicago: To say that I maintain that sugar is more important than insulin in the treatment of diabetic coma is a misquotation and a misinterpretation. The prime need of the comatose patient is for insulin, and the first and most important thing to do is to administer adequate dosage of it. But granting the importance of insulin does not mean that carbohydrate is harmful. Dr. Root naturally sees mistreated cases when he is called in consultation by doctors who have got into trouble. It is true that they were given sugar, but the mistreatment consisted not in what they were given but in what they failed to get, namely adequate insulin and sodium. Why blame the carbohydrate? A fairer comparison with his own patients would be with a group treated by competent physicians or clinics, who have received sugar as well as adequate amounts of insulin and sodium. I am well aware of the fact that many cases of coma can be treated successfully with insulin alone. But the import of Dr. Root's statistics depends on what he calls diabetic coma. How deep was the coma? How long were the patients in coma before treatment was begun? Aside from carbohydrate administration, in what respects were the cases which he saw with other physicians treated less adequately than his own? No comparison is possible unless these questions are answered. As regards the amount of carbohydrate needed by a patient in coma, Dr. Root's calculations completely ignore the carbohydrate utilized in the first twenty-four hours, as the patient's metabolism reverts to normal under the influence of the administered insulin. Taking this into account, I have calculated that the comatose patient requires about 500 Gm. of carbohydrate in the first twenty-four hours and about 250 Gm. per day thereafter. With a low carbohydrate intake, 1 unit of insulin will be "equivalent" to 1 or 2 Gm. of carbohydrate, while on a high carbohydrate intake 1 unit of insulin may be "equivalent" to as much as 10 Gm. of carbohydrate. Dr. Root's neglect of this fact is similar to that of the chemist

who seeks to speed up a reaction by adding a catalyst but forgets that the rate of reaction is proportionate to the concentration of the substrate. In the treatment of coma I agree wholeheartedly that the most important and the first thing to do is to give insulin. But once this is done there are a number of other things which should be done in order to treat not just the coma but the whole patient. One of these is the restoration of fluids to counteract dehydration and hemoconcentration. Another, especially when the kidneys are in difficulty because of the lack of sodium, is to administer salt or alkali. And certainly still another is the administration of the carbohydrate which the patient needs for his metabolism and to restore his glycogen reserves.

DR. FREDERICK M. ALLEN, New York: It is difficult to condense into a few words my general agreement with Dr. Root and Dr. Joslin regarding the ideal of strict control of diabetic sugar, together with some doubts concerning the positive conclusions on acidosis. These clinical results are admirable and unequaled, but clinical statistics may not always establish general theories. One illustration is the amputation mortality cited in some of these meetings. Is the New York surgeon with 6 or 7 per cent mortality five or ten times as good in his methods as his colleague with five or ten times that death rate, and is Boston with a 3.6 per cent mortality twice as good as New York's best? Our hospital has more deaths than that from cardiac complications alone. Yet we feel sure that our 15 per cent of deaths under refrigeration demonstrates a real improvement and that refrigeration might save some of the few desperate cases included in the mortality elsewhere and ease convalescence for the others. Since I was long ago authoritatively prevented from continuing diabetic experimentation, I can only ask a series of questions about acidosis. Is every diabetic coma in man or dog curable at every stage? Is there a terminal stage of shock, as I formerly suggested, which is fatal in spite of clearing up of sugar acetone and without any fault of the physician's method? As to coma being due solely and invariably to lack of insulin, what about the fatal ketosis of normal fasting puppies and the coma produced in the pre-insulin era by suddenly withdrawing carbohydrate from certain diabetic patients? Does excess of glucose in any degree inactivate insulin, reduce carbohydrate utilization or increase fat metabolism? Is not the opposite more credible? Theoretically, I doubt that glucose would increase mortality. During the brief clinical crisis of coma, physicians without immediate laboratory facilities may be bolder with huge insulin doses if they are assured against hypoglycemia by moderate glucose injections. Granting intelligent administration without excesses, is glucose by vein necessarily more harmful than the carbohydrate which Dr. Root very properly feeds as soon as possible?

DR. HOWARD F. ROOT, Boston: I wonder if Dr. Allen has read the case of Grunberg and Rhodes. Their boy, admitted in early coma, was given glucose, with the result that in the next twelve hours he became moribund and the blood sugar tested every few hours reached the level of 1,600 mg. The total insulin requirement rose to 1,600 units. Patients who are totally unconscious are certainly in a more serious condition than coma patients who have not yet reached that stage. Yet even this classification may be deceptive. A child with relatively little ketosis may be unconscious because of an accompanying infection. A patient with rapidly advancing acidosis may walk and respond to questions, yet after recovery he remembers neither the gastric lavage nor any other details of his treatment. The administration of glucose may neutralize the effect of insulin in coma and therefore greatly increase the amount required. It is common knowledge that, when hypoglycemia has been caused by an overdose of insulin, glucose neutralizes the effect of insulin. Dr. Soskin would force on a critical coma case in twenty-four hours 500 Gm. of glucose. I doubt that many men in treating diabetic patients who are on their feet and doing their daily work would urge on them 500 Gm. of glucose a day. I would prefer that we enable him to utilize the extra glucose circulating in his body fluid by administering insulin and then as he recovers begin to feed him. Figures for the utilization of carbohydrate in terms of grams per unit of insulin are entirely unreliable during diabetic coma because of increasing insulin resistance.

ALCOHOLISM

A SOCIAL DISEASE

D. B. ROTMAN, M.D.

Director of the Psychiatric Institute of the Municipal Court
CHICAGO

At times of maximum stress and strain, such as is the present, we can expect big things to happen. No one doubts that the psychologic tensions released by World War I made possible the introduction in this country of modified prohibition in 1919, which in turn paved the way for the absolutisms of the Volstead Act in 1920. Many argue that, because the bad tastes of that era still linger on, that which did happen once, and so disastrously for all, could not possibly happen again. Yet it is the opinion of the Research Council on Problems of Alcohol of the American Association for the Advancement of Science that there are now indications of another drift toward prohibition.¹ Prohibition may or may not be lurking around the corner, but one need not be labeled an alarmist to insist that the problems of alcoholism were never more acute or pressing to this nation, mobilized as it is in both its manhood and its womanhood for total warfare. Any statistical statement concerning the size of this problem cannot help but be an understatement. It is easy enough to tabulate the worst chronic alcoholic addicts, especially those in the lower economic brackets, who gravitate to the courts and the state hospitals, but the more vexing aspects of the problem occur in the groups who have social and economic prestige and remain therefore statistically sequestered. H. W. Haggard's and E. M. Jellinek's suggested figure of 600,000 pathologic drinkers against a drop curtain of 40,000,000 users of alcohol is certainly a conservative estimate at least as to the number of problem drinkers.

As every acute and chronic alcoholic addict is actually a sick person, the treatment of alcoholism naturally becomes a major medical problem. As alcoholic indulgence ultimately affects in turn all of the vital organs, including the central nervous system, medical scrutiny has disclosed a wide range of clinical manifestations which in their aggregate have come to be known as "the alcoholic diseases." These diseases, either alone or in combination, set up such formidable medical problems as to tax the ingenuity of the general practitioner and his various consultants. Great progress has been made concerning the true etiology of these alcoholic diseases, particularly the role that the vitamins play in their causation. It is certainly a feather in the cap of the neuropathologist that he has been able to establish conclusively that the involvement of the peripheral nervous system by alcohol is a neuropathy (a degenerative process due to the absence of essential vitamins) and not a bona fide neuritis (an inflammatory reaction in the nervous system set up by the presence of the alcohol). Such findings have practical value in that the use of certain specific vitamins has come to play an important role in the prophylaxis and therapeutics of these diseases. But in our enthusiasms for the vitamin approach let us not forget that this type of treatment is capable of combating only the organic complications of alcoholism. Obviously they cannot alter, or even touch, its primary and essential aspects. The

vitamin panacea has conjured up nowhere a more treacherous mirage, than in the alcoholic sector.

There are many definitions for alcoholism; one is as good as another. For our purposes any individual who exhibits a strong psychologic affinity for any one or more of the many alcoholic products, coupled with an inordinate physiologic vulnerability of his body-tissue to them, may be considered an alcoholic addict.

It is the latter half of this definition, dealing with the tissue vulnerability, that made it necessary to call on the medical and allied disciplines for possible solution. It is to these alterations in the body tissues that those of the biologic sciences have directed their major research. Appreciating their limitations, medical men have in turn been forced to call on others than biologists with a hope that a better understanding of the psychologic antecedents may be disclosed.

The psychologic aspects of the problem, as they gradually emerge, have become more and more intriguing. Research aiming at the delineation of a unitary alcoholic personality has up to date led all of us into a cul-de-sac. Efforts to squeeze the alcoholic addict into the established categories of personalities have been futile. Many have thought that because of the periodicity in the drinking of some alcoholic addicts (dipsomaniacs), and also because in many families epilepsy and alcoholism seem to be genetically linked, alcoholism must be epileptoid in character. However, according to Lennox,² electroencephalographic studies seem to refute such a concept. The epileptic and half of their near relatives demonstrate a characteristic dysrhythmia in their brain waves. No such findings have been demonstrated in the case of the alcoholic addict and his family. Definite conclusions along this line are to be held in reserve, as yet. Lennox² conservatively states that this phase of the problem is ripe for further investigation. Phyllis Wittman,³ using the Humm-Wadsworth temperament scale, compared a group of chronic alcoholic addicts with a control group. She found no outstanding epileptoid traits in the experimental group, 68 per cent of whom gave a definite history of periodic drinking.

Because of the surface affability of many alcoholic addicts and because of the "slap you on the back tendency" of most of those who are acutely intoxicated, some investigators had been inclined to believe that alcoholic addicts are cyclothymic (of extrovert tendencies). The majority of the students of the problem who have dug deeper have come up quite definitely with the schizoid (introvert) answer. Strecker⁴ sums this all up: "Contrary to the general and lay public opinion, the alcoholic is not so likely to be a hail fellow well met; the alcoholic is apt to be preponderantly introvert." Billig and Sullivan,⁵ in a Rorschach study of 40 alcoholic addicts, point out the basic introvert component present in a high degree even in a subgroup whose excellent adjustment seems to be attributable to extrovert relationships. This introvert tendency in an alcoholic addict

has a strong prognostic influence and is found in many of the cases that prove refractory to treatment. This is easily seen in the notorious example of the "solo drinker" and in all alcoholic addicts who prefer to indulge stealthily and in privacy.

In general, the Rorschach test, that *pièce de résistance* of the modern clinical psychologist's armamentarium, emerges out of the alcoholic confusion in a state of virtual stalemate. Klopfer and Kelley,⁶ authoritative American exponents of this test, are rather laconic and not too informative as they state "In general chronic alcoholics show no typical Rorschach pattern except that most chronic alcoholics yield Rorschach records which deviate considerably from the so-called normal."

As is to be expected, the psychoanalysts have stuck their tentacles into the problem. Their research has undoubtedly helped to illuminate, in some degree, the subterranean passages wherein lurk the conflicts from which the sufferer may be presumed to be seeking release through the narcosis of alcoholism. Schilder⁷ is responsible for a neatly turned epigram which he credits to Simmel, to wit, "Alcohol dissolves the superego (the individual's personal and social consciousness)." This is indeed a nice phrase, but any one who has witnessed the physical and mental tortures brought to light in the phenomenon known as the "morning after hang-over," wherein the superego is reprecipitated with such a catastrophic vengeance, could hardly take stock in the epigram.

Naturally the sex angle has been brought into the limelight by the analysts. Those who are addicted to the use of alcohol, according to them, are persons of immature sexual development. The analyst's slant is most properly epitomized in these arbitrary words credited to Abraham by Lewis:⁸ "Every alcoholic bout is tinged with homosexuality." The clinical confirmation of this alleged latent homosexuality seems to come from the observation that by far the greater number of male alcoholic indulgence is done in male company. Lewis⁹ nails this and a similar observation by Tausk to the mast thus: "Apparently this was written to the world not yet acquainted with our postprohibition excesses in women, where mixed drinking parties are the rule rather than the exception." At any rate, until the analysis can come forth with a broad cultural and educational program capable of whipping the inherent defect in the alcoholic addict's libido into more proper social channels or can furnish us with enough therapists to treat the individual alcoholic addict their pronouncements must be regarded as a species of name calling.

While discussing sex it is interesting to note some facts concerning the ratio of male and female alcoholic addicts. Myerson¹⁰ states that the ratio of female to male alcoholic addicts is 1:7 or 1:8. Jellinek¹¹ places it at 1:6. Both of these writers attribute this ratio to the strictures of our social mores, which attempt to hold women down. In Switzerland the ratio is said to be 1:12, in Norway 1:23 and in England 1:2. Columns 5 and 7 of the accompanying table and the

terious by-product of the social movement known as feminism, which has reached its peak in the varied war activities and responsibilities of women? In passing it may be noted that this 1:2 ratio approximates that of England. In fairness it must be noted that this represents a sex ratio in only extremely pathologic cases.

Much has been written about the sadism-masochism elements of the problem. It is my belief that frequently an alcoholic situation arises out of a sadistic-masochistic imbalance. Clinical observation leads me to believe that the most constant phenomenon in the entire alcoholic picture is the symbiotic relationship between a person addicted to alcohol and a nearby person of an extremely masochistic makeup. In this secondary shadow individual the submissive and masochistic elements in the personality structure are so hypertrophied as to merit the descriptive phrase "a doormat personality." This doormat personality hovers over the alcoholic addict in the dual capacity of a foil and a cushion. To the male alcoholic addict the doormat personality often is an aged and widowed mother, a spinster sister or a wife. To the female alcoholic addict the doormat personality is frequently a second or a third husband or a common law husband or a paramour acquired in her descent down the ladder of deterioration. Unfortunately we are now seeing this mechanism working to the disadvantage of the overseas soldier, whose allotment to the delinquent wife and mother at home is used by her as an opening wedge into a novitiate of a chronic alcoholic career. Once this relationship to the doormat personality is solidified, not much in the way of reversal of the situation can be expected.

Prior to the war we had all come to a critical pass with regard to drinking and automobile accidents as well as to drinking and industrial mishaps. An underlying neurosis seeking release of tension through alcoholism seemed to be the link in these allied phenomena. When we removed the mask of alcoholism, under which accident proneness was parading, frequently there stood revealed the underlying neurosis. Because of the seriousness of automobile accidents the safety of the highways demanded that highly punitive legislative steps be instituted. These legislative acts were climaxed by the introduction into court procedure of the drunkometer

and similar instruments purposing to gage the degree of intoxication registered in the alcoholic contents of the breath, the urine or the blood of the driver. The introduction of these percentages into the court record bid fair for a time to break the ancient dictum of the law that no person should be asked to testify against himself even though the testimony should be mute and chemical. It is true that the court finally held that such evidence was inadmissible, but the courts did hold that the fact that the driver refused submission to such a test could be introduced against him. These punitive upsurges were undoubtedly halted by the war emergency and the slacking speed rate prompted by genuine patriotism on the part of the motorists. This respite has given the experimental psychologist leisure time scientifically to check up on the influence of alcohol on the human psyche. Out of all the material these simple facts may be noted as being true: (1) Alcohol releases a mild euphoria, (2) there is a clouding of judgment, (3) there is some disturbance of muscular coordination, (4) there is a definite slowing down of choice reaction time. Jellinek and McFarland¹² state that "critical analysis of the total evidence of psychological investigations of experimental intoxication reveal that alcohol has a depressing effect on all psychological functions yet measured and that such stimulation as has been reported in some psychological variables is a pseudostimulation. The initial shortening of simple reaction time after alcohol turned out to be artefacts of averaging. The stimulation of muscular strength by alcohol does not seem to be the physiological effect to the absorbed alcohol. The concentration of will power after alcohol is limited to intermittent will activity only; the evidence points toward an impairment of volition in

Relative percentage of male (solid line) and female (broken line) alcoholic addicts, 1931-1943.

continuous tasks." If all of this is true, what are we to expect in the postwar period, which promises to deluge us with machines, gadgets and push buttons of the sort which will in turn ordain the very minutiae of our living?

12. Jellinek, E. M., and McFarland, R. A.: Psychological Experiments on Effects of Alcohol, *Quart. J. Stud. on Alcohol* 1: 272-371 (Sept.) 1940.

Whatever alcoholism is or is not, its universality makes it something of the people, and its partial solutions can very properly be expected to come from the people. What other explanation do we have of the phenomenal growth of the Alcoholics Anonymous? This organization in a short period of ten years has embraced over 12,000 ex-alcoholic addicts. Although we must agree with its leaders in giving religion the most of the credit for the success of this movement, I think we must look deeper if we are to understand its real worth. Those of us who have repeatedly witnessed the failure of the purely religious approach, that is the alcoholic addict's pledge to his clergyman, and the failure of treatment of alcoholic addicts in secular institutions, must indeed be skeptical as to the efficacy of the purely religious program. Truly, Alcoholics Anonymous has used religion, but what it has actually done is to implement the best principles of modern mental hygiene simultaneously. Its approach has been entirely positive. Heretofore, we of the profession have treated the alcoholic addict by constantly keeping before him the mirror of his present and ultimate degradation. This was obviously a negative attack. Alcoholics Anonymous courageously reverses this process by pointing out that good citizenship and social decency can be arrived at and sustained by ex-alcoholic addicts. Who are the mentors of the Alcoholics Anonymous movement? They are not Olympiads. Indeed, they are of the common clay of sinners and sufferers: the ex-alcoholic addicts themselves. It is not tenable for these tutors to explain to their pupils how it is possible to refrain from drinking if the mentors do not continue to refrain themselves. By this maneuver a solid foundation to the movement is already set up. It may also be that the doctors and the therapists have been too stern in their attitude toward the alcoholic addicts and have driven them to the bosoms of their fellow alcoholic addicts. This stentorian stand of our profession can be said to be best embodied in the words of Strecker:¹³ "The skilled therapist is strictly impersonal, objective and unemotional and from the very beginning must decline to deal with anything but the mature segment of the personality of his patients, no matter how minute that segment may happen to be." By thus refusing him a narcissistic bargain the therapist in many instances succeeds only in alienating the alcoholic addict from his therapist.

Group psychotherapy is all the vogue today. Its rationale and efficacy was never better demonstrated than in this mass movement known as Alcoholics Anonymous. Alcoholics Anonymous is dynamic and its potentialities for healthy contagion are limitless. It has the spread power of the chain letter. By its extreme efforts to arrive at nondenominationalism it has evolved a naive and beatific level of thinking in which the Deity is pictured as an energy source. The profile of that deity is flexible to meet any individual's need. Borrowing heavily from William James, Alcoholics Anonymous has agreed that the acceptance of this energy source need not be immediate or spontaneous or even emotional. By so doing Alcoholics Anonymous has eliminated the pyrotechnics and pitfalls usually attendant on the sawdust trail type of conversion. Above all it has eliminated the devil from its scheme of things. Any one who has seen a case of alcoholic hallucinosis and has seen the look of terror in the eyes of persons suffering from the

effects of alcohol squirming under the fancied machinations of the devil and his cohorts can appreciate the subtle therapeutic shift of this simple deletion.

What the Alcoholics Anonymous movement needs is a closer cooperation with the medical profession, and what the medical profession needs even more is a closer cooperation with Alcoholics Anonymous. As time goes on the Alcoholics Anonymous movement could stand for a more rigorous bookkeeping system in its credit and debit ledger, i. e. of its successes and failures. It must cultivate a stronger capacity for autocriticism if it is to steer clear of an unrealistic optimism which could easily cause the movement to disintegrate into a species of Couéism.

In 1932, two years before the movement was crystallized, Meyer¹⁴ anticipated such a mass effort in the following words: "A great share of the work, therefore, lies in a better understanding of the social as well as individual resources of satisfaction for the patient. Much of this work of adjustment is carried on upon a strongly individualizing basis; but even then, in the end, there will always be persons who do best when treated in groups, with the help of a sense of belonging, and being accepted, and of sharing the common convictions, whether they be religious or some kind of mystery, and an open treatment turning to the facts as found, and as they are, either under an intimate patient-physician relationship or a more socialized and open survey and utilization of assets and recognition of specific difficulties."

Can the doctor alone solve the problem of alcoholism? The answer is definitely no! More and more because of the many aspects in the problem, which I have only attempted to highlight, we must come to the inexorable conclusion that alcoholism is a social disease and that at best the doctor can be busy with only a segment of the problem. As a corollary to this conclusion we must not allow the doctor to become pessimistic of his role. Indeed it should spur him on to added effort. The medical man has an excellent precedent for a broadening of his vista regarding alcoholism. Only when we ceased looking on venereal diseases as venereal diseases per se and began to look on them as social diseases did we as doctors make real progress in the venereal problems. Working under this large canopy does not mean that we lose our identity as doctors. The greatest advances in specific chemotherapy as far as venereal diseases are concerned have come recently when we have acknowledged the total situation. It is only when we as doctors begin to see the whole problem that we can make our maximum contribution. We cannot but agree with the forthright and frank statement of Carlson,¹⁵ who honestly says "As I see it it is too complex for the biological and medical disciplines." The proper approach to the problem is exemplified in the pioneering efforts of the Yale projects of the Research Council on Problems of Alcoholism, wherein all facets of the problem are under scientific investigation and wherein particular stress is placed on the biologic, psychologic, sociologic, anthropologic and religious aspects. To these efforts the American medical profession should lend its best support.

BENIGN SURGICAL LESIONS OF THE RIGHT COLON

CURTICE ROSSER, M.D.

DALLAS, TEXAS

Although only one fifth of colonic cancers are found in the right colon, the ileocecal coil is the location of the majority of those inflammatory pseudotumors of the abdomen which require surgical treatment. For many years, however, the overwhelming preponderance of lesions originating from infection of the vermiform appendix and its sequelae so overshadowed all others as to prevent the recognition of a variety of rarer pathologic involvements of the terminal ileum and cecum which are now beginning to be identified, classified and differentiated.

Fig. 1.—Thickened, constricted bowel, in tuberculoma of cecum, resembling annular cancer.

Since W. J. Mayo¹ in 1888 reported cases in which perityphlitis gave rise to palpable tumors which were difficult to differentiate from malignant swellings, numerous studies have appeared in the literature. Walters and Synhorst² aptly termed this condition a "ligneous" infection of the cecum, as it is the woody, firm tumor which confuses the diagnostic picture. Other inflammatory tumefactions, however, must be considered

in the differential diagnosis of surgical conditions of this area, chief among which are tuberculoma, simple ulcer of the cecum, the cecal extensions of regional ileitis and nonspecific granuloma of the colon.

My intent in the present discussion is to illustrate these briefly by examples recently encountered.

Hypertrophic Tuberculosis.—This condition of the intestine, restricted chiefly to the cecum, was first described by Henri Hartman of Paris in 1891. It is frequently a primary lesion. The tissue change is characterized by cellular infiltration and excessive fibrosis, with consequent thickening of the wall and constriction of the lumen. The symptoms are local tenderness and pain, occasional bleeding, flatulence and indigestion. If the disease involves a limited area of the large bowel, complete resection is indicated. In the following example it will be observed that the cecal lesion was preceded by a tuberculous anal ulcer and apparently arrested phthisis:

C. A., a white man aged 46, first presented himself in 1941 when a tuberculous anal ulcer was excised with subsequent healing. A fibrous tuberculosis of the left lung was discovered at that time. The patient was seen again in August 1943 with discomfort on the right side and across the lower part of the abdomen periodically for two years and, for six months, occasional fresh blood in the stools. His sputum was negative for tubercle bacilli on repeated examinations. A roentgenogram of the chest demonstrated that the lesion of the left lung was unchanged. A palpable mass was found in the right lower quadrant, and a colon film disclosed an obstructive lesion in the cecum which resembled cancer (fig. 1). The Kline test was negative, and the red cell count was 5,000,000. The preoperative diagnosis, hyperplastic tuberculosis of cecum, was based chiefly on the collateral findings and the blood count. At exploration the cecum was thick and pearly gray with narrowed lumen; scattered tubercles were seen on the last 3 inches of the ileum (fig. 2). An ileocolostomy was done and resection of the right colon was performed twelve days later. The pathologic examination revealed fibrous thickening of the cecal wall and a mucosa replaced by granulation tissue with areas of cellular infiltration and caseation; giant cells were found surrounding these tubercles.

Simple Ulcer of the Cecum.—This was first described a century ago by Cruveilhier.³ While he stated that the condition could occur anywhere in the colon, the great majority of cases which have been reported have been in the cecum, on the mesial side near the valve. The cause is unknown; the diagnosis in no instance has been made before celiotomy or autopsy, and every patient not operated on has died. While less than 50 cases have been reported in the literature, it is probable that numerous unreported or unrecognized instances of this disease have occurred.

Early collected reports of nonspecific colon ulcers attempted the correlation of lesions from all portions of the bowel, including instances of multiple ulceration. Because the cecal ulcers suggest a definite clinical entity more clearly than lesions in the left colon and because the latter may presumably have been the result of ulcerative colitis and other disease processes partial to the left colon, the pathologist now tends to segregate the single, nonspecific, penetrating ulcer of the right colon as more nearly answering the essential criteria for a pathologic entity.⁴

4. Rosser, Curtice: Simple Penetrating Ulcer of the Cecum. *Ann. Surg.* 119:377 (March) 1944.

The condition is encountered in both sexes at varying ages and may first present itself in an acute fulminating phase in which rapid perforation is common. In this stage the symptoms resemble those of acute appendicitis with pain, nausea, tenderness and low grade temperature. The usual preoperative diagnosis under these circum-

Fig 2—Tuberculoma of cecum. Artist's drawing, showing fibrous thickening of cecal wall, superficial ulceration and tubercle formation of mucosa, with tubercles on nearby ileum

stances has been appendicitis. Closure of the ulcer, in the acute stage, is effectual. A second group of cecal ulcers is seen after the condition has become chronic—often after partial perforation has occurred. The presence of tumefaction, constipation, occasional blood in the stool, vague discomfort in the lower part of the abdomen and a filling defect in the cecum has resulted, in the reported chronic cases, in an almost universal preoperative diagnosis of cancer. In the chronic stage, resection of the cecum is usually necessary. In the following case partial perforation had apparently occurred before the patient was first seen:

S W., a white woman aged 65, stated when she was examined that she had observed for some months a cramping pain in her abdomen, especially in the right lower quadrant; slight nausea was present, but the bowel habit was unchanged. A roentgenogram demonstrated a filling defect in the cecum and there was an increase in the leukocyte count, but the erythrocytes were normal in number. A mass was palpated in the right lower quadrant.

At exploration, under the preoperative diagnosis of "cancer of the cecum," the cecum was found to be enlarged, indurated and surrounded by omental adhesions and an ileocolostomy was done.

After a brief period the abdomen was again entered in January 1943, the preliminary diagnosis being "tumor of the cecum." Some free fluid was found; the conditions otherwise were unchanged. The right colon was resected at this time. The patient had a rather stormy convalescence, associated with irregular temperature. Pathologic examination revealed a firm ulcerated area (fig. 3) in the cecum 2.5 cm. from the base of the appendix. The wall of the cecum was thick-

ened and the peritoneum of the terminal ileum was thick and rough. Microscopically it was seen that the ulcer extended through all the layers of the cecum, its base consisting of granular tissue infiltrated with leukocytes with scattered round cell infiltration in the adjacent tissue. No evidence of any specific etiologic agent was found. Sections of the ileum revealed normal mucosa with infiltration of the serosa and submucosa with lymphoid cells. One lymph node was examined and revealed hyperplasia of the reticuloendothelial elements. The pathologist's diagnosis was simple ulcer of the cecum with partial perforation and subacute pericecitis and peri-ileiti-

Regional Ileitis.—This is a granulomatous proliferative process of chronic inflammatory nature which, by preference, begins at the ileocecal valve and extends upward along the terminal part of the ileum; direct extension to the cecum and ascending colon occurs frequently, which is in part responsible for the suggestion that "regional enteritis" is a better name for the lesion. Its symptom complex is characterized by pain in the right lower quadrant of the abdomen, diarrhea, fever, occasional obstructive phenomena and the formation of fistulous tracts to nearby viscera or the abdominal wall. Young men are commonly afflicted, the average age, according to Crohn,⁵ being 27.6 years.

In the acute form the bowel is red and swollen, with adherence to the omentum and adjacent peritoneum and is associated with soft, enlarged mesenteric lymph nodes. When the chronic phase is reached, the patient has lost appetite and weight and has a chronic incomplete obstruction and not infrequently a palpable mass which consists of gray, soggy, edematous, adherent terminal ileum and cecum

Fig. 3—Simple penetrating ulcer of the cecum. The window demonstrates the area and type of ulceration; the thickened wall and the attachment of the omentum is also shown

The treatment is surgical and consists in radical removal of the portion of the bowel involved. Lahey⁶

5. Crohn, B. B.; Ginzburg, L. and Oppenheimer, G.: Regional Ileitis: Pathologic and Clinical Entity, J. A. M. A. 99:1323 (Oct. 15) 1932.

6. Lahey, F. H., and Sanderson, E.: Lesions of the Right Colon Involving Right Colectomy, J. A. M. A. 120:1356 (Dec. 26) 1942.

has suggested that this may be done in one stage if, as is often the case, the abdomen has been entered recently and in the process of appendectomy a protective vaccination accomplished.

In the following case the pathologic process was observed in its acute phase at the time a preliminary anastomosis was done, and six weeks later, when the abdomen was entered for resection of the involved bowel, the lesion was seen to have become chronic:

P. C. P., a white man aged 28, had a history of chronic ulcerative colitis of the left colon with recurrence over a prolonged period. This condition had recently been brought under control. Six weeks before operation, however, diarrhea recurred, associated with intermittent fever and pain in the right lower quadrant. Roentgen examination of the bowel disclosed a contracted terminal ileum. No definite mass could be palpated. In June 1943 the abdomen was entered and an ileotransverse colostomy performed. The last 8 inches of the ileum, the ileocecal valve and the first 2 inches of the cecum were seen to be thick, red and corrugated and a number of soft glands were palpated in the mesentery (fig. 4).

Following the anastomosis the patient continued to manifest increased temperature, complain of right abdominal pain over a palpable tumor and to lose weight. A fistula developed in the wound. In August the terminal ileum and right colon were resected. At this time the involved bowel was found to be gray, very thick and soggy in appearance, with a very narrow lumen (fig. 5). Examination of the tissue revealed that the specimen consisted of the right colon and 38 cm. of the terminal ileum. The surface of the cecum was smooth, glistening and grayish pink to dark red; its wall was thick and firm. The appendix was found to be firmly adherent to the cecal wall, and there was pronounced thickening in the region of the ileocecal valve,

Fig. 4.—Regional enteritis: Acute phase, showing swelling of the terminal ileum and cecum, with corrugation of the surface and enlarged soft mesenteric glands.

the lumen being considerably constricted in this region. The mucosa was smooth, glistening and grayish pink. Rugae were present and no ulcerations were noted. The wall of the ileum was much thickened, varying from 2 to 3 cm. The mucosa was smooth, glistening and grayish red. There were multiple superficial ulcerations with several polypoid-like projections into the

lumen and also multiple yellowish white, granular appearing areas on the surface. In between the areas of ulceration there were cordlike elevated areas in the mucosa. There were multiple enlarged glands throughout the attached mesentery. Microscopically the mucosa consisted of straight tubular glands, which in many areas were completely surrounded by thick massive

Fig. 5.—Regional enteritis. Chronic phase, showing thickening of wall of cecum and terminal ileum. Extreme constriction of lumen of small bowel, erosion and ulceration of mucous membrane.

infiltrations of polymorphonuclear neutrophilic leukocytes, eosinophils, plasma cells, macrophages and lymphoid cells. These tubular glands were composed of simple columnar cells, most of which were of the goblet type. The ducts of these glands and their crypts were filled with mucus. In many areas there was necrosis of the mucous membrane with ulceration. The ulceration in some of the sections extended through the corium and into the submucosa. In the areas where the mucous membrane remained intact there was increased vascularity, and the submucosa likewise showed pronounced infiltration with the cells enumerated. The aggregate lymph follicles of the ileum were almost entirely destroyed and replaced either by masses of eosinophils, polymorphonuclear neutrophilic leukocytes, lymphoid cells, macrophages or adipose tissue. In the areas of the submucosa where polymorphonuclear infiltration was not so massive there was increased proliferation of the fibrous connective tissue. The muscular layers also showed diffuse cellular infiltration and fibrous tissue proliferation which resulted in a thickening of the muscular walls. Section of one of the lymph nodes showed the capsule and architecture of the node to be intact, but there was definite proliferation of the centers. The pathologic diagnosis was regional ileitis, cecitis and colitis. The patient died eighteen days after the resection from a pulmonary embolus.

Objection has been raised⁷ to separating from this granulomatous, progressively extending and migrating disease involving the bowel wall a rarer group of massive, localized, nonspecific neoplasms which occur in the colon and in other portions of the bowel, but Crohn⁸ believes that, although the etiologic agent may well be the same, the gross appearance, anatomic loca-

8. Crohn, B. B.: Personal communication to the author in May 1942.

tion and dissimilar method of growth and extension warrant their separate consideration.

Moyulhan⁸ in 1906 described six inflammatory tumors of the large intestine which, before exploration, he confidently expected to be cancers and differentiated these tumors from tuberculosis. In 1908 Mayo-Robson⁹ described 11 such cases, some found in the cecum and large intestine, and later Braun⁹ added 3 instances of granulomas of the splenic flexure to the previous experience.

Localized nonspecific granulomas of this type, while of unknown origin and while presenting a microscopic picture somewhat resembling regional enteritis, do not cause diarrhea, stricture and fistulous tracts; they tend to increase in size while remaining at one area in the bowel. I encountered a neoplasm of this type two months ago in a man aged 74 who for one year had noticed constipation, flatulence, indigestion and cramping in the lower abdomen and who, on examination, was found to be anemic and underweight and to have a firm palpable tumor in the right lower quadrant of the abdomen. When the right colon was removed by the Lahey technic, the tumor so resembled an adenocarcinoma, because of its texture, indurated surface and absence of change in the adjacent bowel (fig. 6) that the pathologist's report was the first intimation that the lesion was benign.

It is difficult to suggest a clearcut diagnostic differentiation between cancer and these inflammatory conditions because of such common factors as tumefaction, similar roentgenographic appearance and chronicity.

Fig. 6.—Nonspecific granuloma of cecum, encountered in white man aged 74. Terminal ileum and remainder of cecum are normal.

All of the latter, however, are usually associated with some temperature elevation and with increased leukocyte count; anemia is not pronounced, and the tumor is usually more sensitive. It is perhaps quite fortunate

that surgical intervention is indicated in each of these conditions, because if a patient has received the extended and adequate preparation now considered essential in large bowel surgery before the abdomen is entered, any discrepancy in the preoperative diagnosis can be safely corrected and the proper procedure instituted at the time of surgery.

ABSTRACT OF DISCUSSION

DR. WALTER A. FANSLER, Minneapolis: The largest single series of cases of solitary ulcer reported is 15, and in none of those was the correct diagnosis made. Of those 15 cases there was a diagnosis of appendicitis in 6, peritonitis in 2, intussusception in 1 and carcinoma of the cecum in 1. Ten of the cases had perforated at the time of operation. There were 9 deaths, 5 were cured and 1 result was not stated. In 4 of the 5 recoveries, perforation had not occurred. I can add 1 case to this group: A woman aged 47, whose first complaint was a hemorrhage from the rectum with numerous dark clots seven months preceding examination, observed no more blood until two days previous to examination. Proctoscopy was negative except for some dark digested blood in the rectum. There was no history of diarrhea. Her temperature was normal, and, as far as could be found from the family physician, she had not had any elevation of temperature. Hemoglobin was 11.7 Gm., or 71 per cent, erythrocytes numbered 3,400,000, the white blood cell count was 7,200 and the differential count was normal. A hard mass about the size of a golf ball could be felt in the region of the cecum. This was freely movable and was not tender. My diagnosis was probable carcinoma of the cecum, and the roentgenologist agreed. A double barreled ileocolostomy was done as described by Lahey. On opening the bowel I found a sluggish cratered ulcer. The walls surrounding the crater were approximately 1.5 cm. thick, gradually thinning out toward the periphery of the induration. It had a gross appearance of a chronic ulcer one sometimes sees in the stomach. The microscopic examination showed chronic inflammatory changes with leukocytic infiltrations which extended down to the serosal surface. The patient made an uneventful recovery. The point I wish to make in this discussion is that in ulcer of this type there is no possible method of making a differential diagnosis between this condition and carcinoma of the cecum. Therefore the possibility of this condition should be kept in mind in preoperative conversation with patients.

St. Jerome and Vitamin A.—The following passage, taken from St. Jerome's "Life of St. Hilarion," which was written about A. D. 392, appears to be the earliest account of the etiology, symptoms and cure of severe vitamin A deficiency: "From his thirty-first to his thirty-fifth year he had for food 6 ounces of barley bread, and vegetables slightly cooked without oil. But finding that his eyes were growing dim and that his whole body was shriveled with an eruption and a sort of stony roughness (impetigine et pumicea quadam scabredine) he added oil to his former food and up to the sixty-third year of his life followed this temperate course, tasting neither fruit nor pulse, nor anything whatsoever besides." This combination of an eye affection, nightblindness or perhaps xerophthalmia, with a severe hyperkeratosis precisely resembles the condition described by Frazier and Hu (*Arch. Dermat. & Syph.*, 33:825, 1936) as occurring in Chinese patients who had received a diet not unlike that of St. Hilarion, namely a cereal other than wheat, white cabbage and salted vegetables. These patients were speedily cured by cod liver oil or carotene; and it seems probable that crude and unpurified olive oil, such as St. Hilarion would have permitted himself, would contain enough of the fairly high vitamin A content of the olive to relieve his symptoms and maintain good health. The evident accuracy of St. Jerome in this particular may induce further study of this interesting biography.—Taylor, F. Sherwood: St. Jerome and Vitamin A, *Nature*, Dec. 23, 1944, page 802.

THE INFLUENCE OF GYNECOLOGIC DISORDERS ON THE URINARY SYSTEM

J. MASON HUNDLEY JR., M.D.

AND

WILLIAM K. DIEHL, M.D.

BALTIMORE

As can be readily understood, the presentation of such a comprehensive topic requires the elimination of many of the self-evident phases which are so well covered in the various gynecologic textbooks. For a number of years we at the Hospital of the University of Maryland have been greatly interested in the various changes in the urinary system, particularly those due to pelvic and obstetric conditions. With us, female urology is a division of gynecology, for by this union we feel that the gynecologist is singularly fitted for the evaluation and treatment of urologic problems occurring in women. One of the most important factors in the treatment of any urinary lesion is a careful preliminary pelvic examination in order to rule out the presence of gynecologic disorders which may be evidenced only by urinary manifestations. It is not uncommon for a patient with frequency and dysuria to have the bladder and trigone treated while the causative factor is a moderate sized myoma on the anterior uterine wall.

The subject will be discussed in relation to the three most important etiologic factors. The first and probably the most outstanding is the changes produced by pressure. Several years ago we published an article on the physiologic changes occurring in the urinary tract during pregnancy,¹ and, as the changes in the urinary system associated with the developing pregnant uterus are so frequent and so typical, a brief review of this work will be of value, for lessons here learned also apply to other etiologic factors which are of a pathologic nature.

For many years it has been known that dilatation changes occur in the urinary tract during pregnancy, but it was not until the development of intravenous urography that we have been aware of its nearly constant occurrence. In our urographic study of 27 normal pregnant women throughout the succeeding months of gestation and the puerperium, the most constant change noted was a dilatation of the pelvis and calices of one or both kidneys, a dilatation, tortuosity and kinking of one or both ureters, and a lateral displacement of these structures. In addition, there was an apparent atony of the ureteral musculature observed. Every patient showed some deviation from the normal, the right kidney and ureter being more affected than the left. The dilatation of the ureter always began at the pelvic brim and in not 1 of the patients studied was there found a definite and significant dilatation of the pelvic portion of this structure. With the advance of pregnancy the dilatation of the upper urinary tract gradually increased to the time of delivery, and following this event there was a rather rapid regression to the normal state, taking place as a rule in twenty-eight days. It is a well known fact that the presence of frank infection greatly retards this normal involution process. In this urographic study it was found that with the progressive dilatation of ureter and pelvis there

was an associated retardation of the excretion time of the kidney, so that a delay of thirty to forty-five minutes was necessary before a satisfactory film could be obtained. Associated with this delayed excretion time there develops an apparent increasing atony of the ureteral musculature. We believe that dilatation of the ureter is produced by two factors; first, changes in the ureter due to hormonal stimulation, as shown by muscular hypertrophy, increased vascularity and loss of tone. This changed, succulent tube is then subjected to the pressure of the semicystic, pregnant uterus at the pelvic brim, with resulting dilatation. We feel that if the primary hormonal changes had not taken place the soft, vascular uterus could not exert sufficient pressure on the dense wall of the ureter to produce dilatation. From microscopic studies we have previously shown that the ureter during pregnancy undergoes rather constant and typical changes. One of the most striking of these is the pronounced muscular hypertrophy of the sheath of Waldeyer, i. e. the outer longitudinal layer of musculature which invests the lower 3 to 6 cm. of the pelvic ureters. There is also seen muscular hypertrophy throughout the length of the ureter, confined for the most part to the circular layer. The ureter becomes vascular, soft, dilated and ribbon-like. The opinion has been advanced that this hypertrophied sheath of Waldeyer

Fig. 1.—Peristaltic changes throughout pregnancy.

is the important causative factor in dilatation of the ureter. If this is correct, the dilatations should be bilateral and should begin at the bladder. Our findings have not supported this view, for, as already stated, the changes always begin at the pelvic brim and the right ureter is much more affected than is the left. This increased incidence of right ureteral involvement is due to dextrorotation of the uterus, to cushioning of the left ureter at the pelvic brim by the overlying sigmoid and also to the fact that the right ureter crosses the pelvic brim nearly at a right angle, making it more vulnerable to pressure. The course of the left ureter is much more of a straight line and is consequently less subject to pressure effects. We believe that the vast majority of investigators are now of the opinion that dilatation of the ureter at the pelvic brim is due to pressure, this being the concept originally promulgated by Opitz in 1905. We feel that this theory was definitely proved by the experiments we conducted with the use of the indwelling catheter during the later stages of pregnancy. It was shown that if continuous drainage of the upper urinary tract with the indwelling catheter was maintained for forty-eight to seventy-two hours there was a definite regression of the dilated pelvis and abdominal ureter.

Is there sufficient evidence to support our views that the urinary tract is subject to hormonal stimulation? We feel that the following data do support this opinion, which is of scientific as well as of clinical interest.

Read before the joint meeting of the Section on Obstetrics and Gynecology and the Section on Urology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.
1. Hundley, J. M., Jr., and others: *Am. J. Obst. & Gynec.* 30: 625, 1935.

When one considers the embryologic development of the generative and urinary systems, the two arising from the same anlage, it does not seem too hypothetical to believe that the hormonal influences elaborated during gestation could affect the two systems in the same man-

Fig. 2.—Base line tracing before treatment with diethylstilbestrol.

Fig. 3.—Increase of peristaltic activity following six weeks of diethylstilbestrol therapy.

ner. As already mentioned, one of the most outstanding evidences of hormonal activation of the urinary tract is that of the pronounced hypertrophy of the musculature throughout the ureter and especially in its lower end, namely the sheath of Waldeyer. This cannot be considered a work hypertrophy, for we found these same hypertrophic changes in a patient dying following an operation for an ectopic pregnancy of seven weeks' duration, when it was impossible to have pressure because of the small size of the uterus. Other evidence to support this hormonal theory is presented by the autopsy findings of a man dying from a teratoma of the testicle with generalized metastasis, which proved to be a chorionepithelioma. Prior to operation the urine had been strongly positive for anterior pituitary-like substance on two occasions. The examination of the ureter showed definite hypertrophic changes throughout the entire organ but was most evident in the juxtavesical portion. Here there was tremendous hypertrophy of the sheath of Waldeyer, the greatest external diameter measuring 8 mm., the measurement of the normal non-pregnant ureter in the same location being about 3.5 mm. Another factor that seems to support the endocrine theory of ureteral activation is that following delivery, and with the rapid decrease of the hormonal content of the urine due to the absence of the placenta, the main source of estrogenic and anterior pituitary-like substances there is a progressive and rather rapid regression of the urinary tract to its normal state. Knowing of the work of Traut and McLane on ureteral peristalsis during pregnancy, we wished to confirm if possible their observations, for we felt that the peristaltic variations they noted might be dependent on hormonal influences and not on muscular work fatigue, as might be supposed. If we could demonstrate that these variations were due to hormonal influences we would then have additional confirmatory data to support this hormonal theory as an

etiologic factor in ureteral changes. We found, as they did, that there is an increasing atony of the ureter with advancing pregnancy and that beginning with the end of the second trimester there is a complete loss of tone, with absence of peristalsis. There is a return of peristalsis just prior to parturition, which then continues on through and after the puerperium. Figure 1, a composite graph, depicts the peristaltic changes throughout pregnancy.

In order to carry out these experiments on ureteral peristalsis, Trattner's hydrophorograph was used. The details of the procedure are given in the original article.² After completing this study of ureteral behavior during pregnancy and observing the very striking atonia that developed, we then attempted to prove that the peristaltic activity and atony were dependent on hormonal influences. We know that during pregnancy large amounts of estrogenic and progestogenic substances are elaborated in the placenta. The estrogenic substance produces growth and also causes contraction of the uterus, whereas it is generally thought that the progestogenic substance allays uterine activity. By priming normal women with large and prolonged doses of estrogenic and progestogenic substances we hoped to simulate in a measure hormonal conditions that exist during pregnancy and possibly produce the same ureteral behavior that normally occurs during this period. A brief summary of the experimental results follows: Eight normal women were treated with diethylstilbestrol, each receiving orally 2 mg. twice daily over a period averaging ten weeks, the patient thus receiving a total of 280 mg. Weekly hydrophorographic tracings were

Fig. 4.—Base line tracing prior to progestogenic therapy.

Fig. 5.—Absence of peristaltic waves following six weeks of progestogenic therapy.

made and there was noted a great increase in peristaltic activity as shown by the great increase in amplitude of the contraction waves. For comparison see figure 2, a base line tracing before treatment with diethylstilbestrol, this being the usual pattern for the normal woman.

2. Hundley, J. M., Jr.; Diehl, W. K., and Diggs, E. S.: *Am. J. Obst. & Gynec.* 44: 558, 1942, from which figures 1, 2, 3, 4, 5 and 6 in the present article are taken, through the courtesy of the American Journal of Obstetrics and Gynecology.

Now compare this with the tracing obtained after six weeks of treatment with diethylstilbestrol (fig. 3). Here is seen a great increase of peristaltic activity.

In order to determine whether allaying of ureteral activity and final atonia developed under the influence of a progestogenic substance, another group of 8 normal women was selected. These women received an intensive course of progestogenic therapy over a period of nine weeks, each receiving weekly proluton 8 mg. intramuscularly and in addition pranone 280 mg. orally, making a total dosage that each received, proluton 72 mg. and pranone 2,520 mg. No symptoms referable to this intensive therapy were demonstrable. Weekly hydrophorographic tracings were made, and there was noted a gradual decrease in the amplitude of the peristaltic waves until complete atonia existed. For comparison see the normal pattern of ureteral activity before progestogenic therapy was begun (fig. 4). Now compare this with the tracing obtained after five weeks of intensive therapy and there will be noted complete atonia, this effect being similar to that observed in the pregnant woman of thirty weeks' gestation (fig. 5). It would seem from these two experiments that hormonal influences play a definite role in ureteral behavior, the estrogenic substance activating the peristaltic contractions and the progestogenic substance allaying these contraction waves.

EFFECTS OF UTERINE AND OVARIAN TUMORS ON URINARY SYSTEM

We have briefly presented the physiologic changes that occur in the urinary tract during pregnancy as well as demonstrating the hormonal influences on this system. Now we wish to consider what effects uterine and ovarian tumors and parametrial carcinoma have on the urinary system.

In a previous publication we reported a group of urographic studies associated with large pelvic tumors, showing preoperative and postoperative changes. We

ureter associated with a large intraligamentous myoma, but we have not seen such a change with a parovarian cyst. In many of the patients with large pelvic tumors intravenous urograms were made before and after operation. A striking example is here shown of the result of pressure due to a large fibroid tumor which had been

Fig. 7.—Dilatation of the ureter due to parametrial extension from carcinoma of the cervix.

present for many years (fig. 6A). The tumor was removed, and thirty-eight days after the operation another intravenous urogram was made (fig. 6B). Here is strikingly portrayed the wonderful recuperative power of the urinary tract once there has been a release of pressure and obstruction.

As is well known, one of the most frequent causes of bilateral hydronephrosis and hydronephrosis is parametrial carcinoma having metastasized from the cervix. In our oncologic clinic approximately 65 per cent of the patients have parametrial involvement with potential associated degenerative changes in the kidney. A common symptom observed in this group of patients is nausea and vomiting associated with a mounting non-protein nitrogen and kidney failure. As the metastatic growth envelops the lower end of the ureter more snugly, complete anuria may ensue, with death occurring as late as ten days after the onset. Pathologic studies show the ureter completely surrounded by growth in its justavesical portion, and above this occlusion there is seen pronounced dilatation of the entire tract (fig. 7).

The second most important factor to be discussed is the pathology of the urinary tract as a result of parturition. As is known so well, multiple and difficult labor are the main factors in the production of relaxations and lacerations of the pelvic floor. Many of these lesions, while minimal during the earlier years, become much more pronounced near or after the menopause. The lesions in which we are here most interested are those that cause some derangement of the urinary tract. The majority of the conditions are true hernias due to stretching and tearing of the fascial supports, and it is

Fig. 6.—Urograms showing (A) pressure effects due to large fibroid tumor and (B) regressive changes thirty eight days after operation.

were able to demonstrate that definite pressure effects, as evidenced by dilatation of the upper urinary tract, were produced when the pelvic tumor was of sufficient size and contour to exert pressure on the ureter, usually at the pelvic brim. Naturally these changes are more prone to occur with the denser type of tumor which is fairly well fixed. It is not uncommon to find a hydro-

more common to have several coexisting lesions than single entities. Malpositions of the uterus with descensus, endocervicitis, cystocele and rectocele are common handmaidens and are all so excellently presented in the various textbooks that only certain aspects will be here discussed. We think we all are in accord that lesions that affect the bladder and urethra are much more provocative of symptoms than those that affect the recto-vaginal septum. A cystocele associated with uterine prolapsus gives primarily symptoms of frequency and dysuria, and occasionally inability to empty the bladder completely if there is a dependent pouch below the urethra. Many patients state that in order to void satisfactorily the prolapsed uterus and cystocele have to be replaced. When a cystocele has existed for years with an associated descensus, cystitis is common, as the result of stasis of urine with resulting infection. Uterine prolapse may also play an important role in the production of hydronephrosis and hydroureter, as reported by various authors. The etiologic factors are due to compression of the lower ends of the ureter either at the point of their herniation through the hiatus genitalis or by the drag of the prolapsed uterine arteries.

Another condition of considerable interest is that of stress incontinence, which is characterized by involuntary spurting of urine on stress or strain; even laughing or coughing may produce this distressing situation. This condition is seen in postmenopausal women with a normal appearing urethral tube and also in women as the result of obstetric trauma, with a subsequent weakening or relaxation of the urethral sphincter mechanism. In the postmenopausal patient who suffers from stress incontinence there is frequently seen a pronounced trigonitis that accompanies the regressive tissue changes due to hypoestrogenism. The urethra is of normal appearance and there is no gaping of the internal sphincter. Topical application of silver nitrate solution of 2 to 3 per cent through the Kelly cystoscope is of great value. As many of these patients are highly neurotic, mild sedation is of great value.

In the treatment of the group due to obstetric trauma, the most satisfactory results can be obtained. Of course, incontinence due to increase of intracystitic pressure resulting, for example, from pressure of a uterine fibroid or pregnant uterus would not be alleviated by an operation on the vesical neck. The same holds true if the dribbling is due to a cord lesion. The operative procedure commonly used with us is the one described by Dr. Howard A. Kelly in 1911. He states that "the key to successful treatment lies at the internal orifice of the urethra and in the sphincter muscle which controls the canal at this point." In brief, the operation that we perform is as follows: An incision is made through the vaginal mucosa, extending from just below the external urinary meatus down within 2 to 3 cm. of the external cervical os, the tissues first having been well infiltrated with salt solution containing 10 minims of epinephrine to the ounce. This infiltration, so commonly used on the continent, greatly facilitates the separation of planes of cleavage and also allays to a great measure venous oozing. Naturally, the resulting hemostasis is more pronounced in the menopausal patients, in whom tissue regression is the rule. The vaginal mucosa is separated from the bladder wall; then, with a little care, the pubocervical fascia can be well isolated. The bladder is advanced well up on the cervix. The next step is to suture the torn or relaxed tissues at the neck of the bladder with interrupted fine silk so as to buttress the vesical neck. The pubocervical

fascia is then brought together as a separate layer, following which any excess of anterior vaginal wall is excised and the wound closed. Many other operative procedures have been devised and are of great value in special cases when there is partial or complete destruction of the vesical neck. Today, with the great improvement in obstetrics, the incidence of vesicovaginal fistulas is of infrequent occurrence, the majority of destructive lesions of the ureter and bladder being due to operative accidents. Some time ago I saw an incontinent patient who had been operated on for an intraligamentous myoma. Immediately following operation no incontinence was noted; however, ten days later urine was noticed escaping from the vagina. The patient still continued to void normally. Careful cystoscopy and methylene blue injected into the bladder revealed no defect in this organ. Catheterization of the ureters demonstrated an obstruction in the left ureter at the brim of the pelvis, the right tract being normal. A urogram revealed periureteral extravasation of the opaque substance at the point of obstruction in the left ureter. With this finding it was obvious that the urine

FIG. 8. Vesicovaginal fistula, showing position of incision

escaped by way of a tract that united with the cervical canal. This was substantiated by giving the patient methylene blue by mouth and then plugging the cervical canal with gauze; the blue stain was found on the left side of the gauze. At operation a left hydronephrosis and hydroureter were found which necessitated nephrectomy.

The following procedure for the repair of very large vesicovaginal fistulas is simple and successful: A young colored primipara had a difficult, prolonged labor and ten days post partum became incontinent. On examination in the hospital a very large vesicovaginal fistula was seen (fig. 8), the base of the bladder was nearly

completely destroyed and the defect would admit three fingers. The surrounding tissues were in good condition, so that the operation could be carried out without delay. The ureters were catheterized and the ends of the catheters were brought out through the urethra and allowed to remain for ten days. As is seen in figure 9 a circular incision was made in the vaginal mucosa about the fistulous opening at a distance of about 2 cm. from the defect. This flap was partially undercut so that it remained attached at the edge of the fistula (fig. 10). These freed flaps of vaginal mucosa then turned back on themselves so as to cover the defect and then sutured vertically one to the other by an imbrication suture, so that the broad surfaces approximated one another. The floor of the bladder was thus lined by the mucosal surface of the vaginal mucosa. The denuded defect (fig. 11) was then united transversely with interrupted number 1 chromic catgut, this being the suture material used throughout the procedure.

The patient experienced an uneventful convalescence, with good union of the tissues, and there was no incontinence.

Another important factor to be considered is the role of adnexal and cervical infections as they pertain to lesions of the urinary system. Adnexal disease causes compression effects on the ureter, depending on the chronicity and resulting fibrosis and fixation of the tubo-ovarian mass. As would be expected with an acute

a study of 100 patients who showed varying gynecologic conditions found that dilatations of the upper tract were frequently associated with chronic salpingitis, subacute salpingitis with masses and pelvic abscesses. The incidence of percentages was 44.4, 58.3 and 57.2.

Fig. 9.—Undercut vaginal flap, remaining attached at edge of fistula, united by imbrication sutures.

Fig. 10.—Closure of vaginal flap nearly completed in vertical line.

The work of Martin Schreiber⁴ on the subject of ureteral stricture, based on the findings in one hundred consecutive autopsies, is of particular interest. From this thorough and painstaking work we quote a partial summary of his conclusions, which are pertinent to this presentation:

1. Stricture of the ureter does exist as a definite pathological entity.
2. A 12 per cent postmortem incidence of stricture or stenosis corroborates the great number of such lesions found clinically.
3. Latent symptomless hydronephrosis due to obstruction are relatively frequent, as evidenced by a postmortem incidence of 10 per cent.
4. Ureteral stricture as a localized intrinsic inflammatory process in the ureteral wall, due to focal infection, is relatively rare.
5. Ureteral stricture or stenosis is found most frequently in the pelvic ureter in a zone 2 to 6 cm. from the ureteral orifice.
6. Important etiologic factors in the production of ureteral obstruction are due to narrowing of a congenitally constricted site, extension of inflammatory processes from adnexal disease with and without thrombophlebitis, advanced chronic cystitis and the occluding kinking power of crossing anatomical structures, namely the vas deferens in the male and the uterine artery in the female.

As we are all aware, the incidence of ureteral stricture varies tremendously with personal interpretation. Many

3. Everett, H. S., and Sturgis, W. J.: *Urol. & Cutan. Rev.* 44: 638, 1940.

4. Schreiber, M.: *Surg., Gynec. & Obst.* 45: 423, 1927.

support their diagnosis of stricture by the demonstration of the "hang" with the wax bulb, others relying more on the finding of dilatation effects as shown by urography. We feel that if a definite stricture exists there should be a resulting dilatation which is demonstrable by urography. However, the fact remains that many patients are relieved of their symptoms following ureteral dilatation even when the urogram showed no abnormality.

Knowing that a considerable difference of opinion exists as to the relationship of endocervicitis to trigonitis and cystitis, we reviewed the current literature and found a paucity of factual evidence on this subject. An experimental article of merit on the transmission of infection from the uterine cervix to the urinary tract has been presented by Winsbury-White.⁵ Some of his findings pertinent to this subject will be presented. He is of the opinion that cystitis and trigonitis are constant companions of cervicitis and that the bladder infection is difficult to eradicate if the cervical lesion is not also treated. Owing to this frequent association of lesions he raises the question as to the existence of a lymphatic connection between the uterine cervix and the trigone. In order to prove his opinion he carried out the following experiments: He injected india ink and living and dead tubercle bacilli into the tissues of the cervix in some animals, and into the urethra in others. His most conclusive results were found by using india ink injections in the cervix of the guinea pig. A summary of the results of experiment 5 is as follows: The guinea pig was killed four days after the injection of india ink. Masses of the pigment were found in the lymphatics of the bladder wall. When injections were made with living and dead tubercle bacilli, inflammatory reactions were found in the bladder wall as well as in the vaginal coats. He concludes that these findings demonstrate a lymphatic connection between the cervix and the bladder as well as between the cervix and the vagina, and "therefore we may expect, as we generally find in practice, that cervicitis is accompanied by cystitis and vaginitis." The remaining portion of the article deals with the upward lymphatic migration of the india ink and tubercle bacilli following their injection into the cervix.

Wishing to determine the relationship between endocervicitis and trigonitis and cystitis, we examined cystoscopically a group of 50 women who had varying degrees of endocervicitis. A summary of this study follows: In order to designate the degree of cervicitis present, the lesions were classified from 1 plus to 4 plus; accordingly, there were found 13 patients with a 1 plus lesion, 19 patients with a 2 plus lesion, 13 patients with a 3 plus lesion and 5 patients with a 4 plus lesion. The bladder symptoms complained of were nocturia ten times and dysuria ten times; in 32 patients there were no urinary complaints. The cystoscopic results are as follows: The bladder mucosa was found normal in 47 patients, whereas the remaining 3 showed a moderate hyperemia. A normal trigone was found in 34 patients, whereas 13 showed slight degrees of injection. One patient showed a bullous edema with 3 plus injection. This definite trigonitis was associated with an *Escherichia coli* communior infection of the urine, and there was an accompanying 4 plus endocervicitis. Two other patients showed similar degrees of trigonitis, and in both *E. coli* was the offending organism. In 1 of these

patients the degree of cervicitis was 3 plus and in the other only 2 plus. Mucosal tags were seen projecting into the lumen of the urethra at the internal orifice in 4 patients. The ureteral orifices were normal in 45 patients. A halo of injection was seen about both ureters in 2 patients, about the right ureter in 2 and about the left orifice in 1. Bladder cultures were obtained from all the patients except 4: negative cultures in 26, or 52 per cent, *Staphylococcus albus* in 8, or 16 per cent, *Staphylococcus aureus* in 2, or 4 per cent, *Staphylococcus fecalis* in 1, or 2 per cent, *Clostridium tetanoides* in 6, or 12 per cent, and *Escherichia coli* communior in 3, or 6 per cent. The cultural findings correspond quite closely to bacteriologic studies made on the bladder urines of the pregnant and nonpregnant women which we have previously reported.⁶ In that study we found that the incidence of all organisms in the bladder urine of the pregnant woman was high, namely 50 per cent. However, this finding lost much of its significance when we noted that the urine of the control nonpregnant

Fig 11—Closure of vaginal mucosa in horizontal plane

group showed 44 per cent positive cultures, this finding corresponding rather closely to the percentage here found, namely 48 per cent positive cultures. The types of organisms isolated in this study were the same as those found in the previous investigation, all normal inhabitants of the vestibule, and we feel that many of these positive cultures are due to the entrance of the organisms into the bladder through the short, rather patulous urethra.

From this study of the relationship between endocervicitis and cystitis and trigonitis we feel that we can draw the following conclusions: Endocervicitis plays

⁵ Winsbury White, H. P.: *Brit J Urol* 5: 249, 1933.

⁶ Hundley, J. M., Jr., and others. *Surg., Gynec & Obst* 66: 360, 1938.

no role as a causative factor in the production of cystitis, for the bladder was normal in 47, or 94 per cent, of the patients. It would seem that the same holds true for trigonitis, for here the trigone was quite normal in 34 patients. As is well known, trigonitis is of very frequent occurrence, often of short duration, and seen frequently with diseases of the urethra, relaxations due to childbirth, postmenopausal regressive changes and many other factors. The evaluation of the trigone as to the degree of hyperemia and whether the mild changes are abnormal is difficult. From this study we feel that there is no significant relationship between pathologic conditions of the cervix and of the bladder. If lymphatic migration of organisms from the cervix to the bladder is of such common occurrence as stated by Winsbury-White, why does not malignant involvement of the floor of the bladder occur more frequently from a carcinoma of the cervix? Carcinoma of the cervix metastasizes as a rule into the parametria, either by direct growth or by lymphatic spread, probably most often by both pathways. We routinely examine cystoscopically all patients with carcinoma of the cervix, and of 413 such patients examined we found bladder involvement in only 54, or an incidence of 13.1 per cent. It is unusual to see direct extension of the growth into the lumen of the bladder. The usual finding is a submucosal extension of the cervical lesion, producing a cobblestone or knobby appearance.

A somewhat unusual but most interesting invasive lesion of the bladder from a gynecologic focus is due to endometriosis, probably produced by the retrograde reflex of endometrial tissue through the oviducts at the time of menstruation. Not all are in accord with this transtubal theory, as presented by Sampson⁷ in his original article in 1921. The so-called celomic metaplasia theory is supported notably by Robert Meyer, whereas Halban believes that lymphatic dissemination is the pathway for dispersion of endometrial fragments. Some time ago such an interesting condition came under our observation. A young woman was operated on by the senior author for bilateral pyosalpinges; both tubes and one ovary had to be removed and, owing to the associated inflammatory changes in the adjacent tissues, the abdomen was drained for a short time. The patient had an uneventful recovery. Later she presented herself for observation, stating that for several months bleeding had occurred from the site of the drain tract in the abdominal wall, though only at the time of menstruation. Gradually a spherical, nodular mass was observed developing in this region, and the bleeding continued to appear from this area only at the menstrual time. A second operation was performed through the original scar, and the nodular mass was found filled with many mulberry-like cysts containing bloody fluid. When the abdomen was opened the pelvic peritoneum was studded with these same small cysts and in the wall of the bladder, at its base, a large nodule similar to that found in the abdominal wall was observed. Unfortunately a cystoscopy had not been performed, but it was definite that an endometrial invasion of the bladder was present. Two methods of treatment presented themselves, either a resection of the bladder, which would have been extensive and difficult, or the removal of the remaining ovary. It is well known that ovarian activity is necessary for

the maintenance and development of these endometrial masses, and with its absence the lesions undergo prompt regression. The remaining ovary was then removed. The endometrial mass in the abdominal scar was excised so as to facilitate a better closure. The patient had an uneventful convalescence, and when later seen the nodular mass in the base of the bladder had disappeared. Unfortunately the patient refused cystoscopy; however, there was no doubt that complete regression had taken place. If this had not been the case, a cycle of high voltage x-ray therapy would have hastened its disappearance, for it is known that this lesion is sensitive to radiation. Occasionally patients with this bladder involvement give a history of intermittent hematuria, but here this was not the case. Microscopic examination of the cystic material confirmed the operative diagnosis.

There are many other conditions that probably could be discussed profitably, but a comprehensive presentation would be far too voluminous for present consideration.

COMMENT

One of the most important factors in the production of urinary tract changes is due to pressure exerted by pathologic processes arising in the female pelvis. We have given a brief summary of our previous findings on the physiologic and pathologic changes in the urinary tract during pregnancy and also have shown what effects estrogens and progestogens exert on ureteral activity. This review is of value, for the lessons here learned are of a fundamental nature and make easily understandable changes produced by pathologic factors. Quite similar dilatation changes in the urinary tract occur in the presence of large pelvic tumors; however, we do not see the hormonal manifestations described as occurring in pregnancy. The dilatations may arise at the pelvic brim or in the pelvic bowl.

The second factor discussed was pathology of the urinary tract as a result of parturition. Here were considered relaxations of the pelvic floor, with special reference to the cystocele and the frequently associated cystitis. It was also shown that uterine prolapse may be an etiologic factor in the production of dilatation of the ureter. A method for the repair of large vesicovaginal fistulas has been presented, in which the surrounding vaginal mucosa was used to cover the defect. Stress incontinence is of frequent occurrence. It is seen in the postmenopausal woman with regressive changes occurring in the bladder and trigone due to absence of estrogenic stimulation. Trigonitis is frequently associated with these regressive changes and is usually alleviated by the topical application of silver nitrate solution 2 to 3 per cent through the Kelly cystoscope. Stress incontinence is also seen as a result of obstetric trauma when there is an associated relaxation and stretching of the fascial supports. The operation devised by Howard A. Kelly is of distinct value, and its success is dependent on the proper buttressing of the vesical neck. Fistulas are of infrequent occurrence, the greatest number resulting from operative accidents and from irradiation of cervical carcinoma. With us, vesicovaginal fistulas due to childbirth are rarely seen.

We next discussed pelvic infections as they influence the urinary system. There is no doubt that chronic disease of the adnexa with or without masses cause pressure on the ureter and by inflammatory invasion produces stricture of the ureter. The work of Schreiber on ureteral stricture showed that adnexal disease was

7. Sampson, J. A.: Perforating Hemorrhagic (Chocolate) Cysts of Ovary. Their Importance and Especially Their Relation to Pelvic Adenomas of Endometrial Type, *Arch. Surg.* 3: 245 (Sept.) 1921.

one of the most frequent etiologic factors in its production. Wishing to determine what role cervical infections played in the production of bladder disease, we selected 50 women with varying degrees of endocervicitis, the majority having no urinary complaints. Cystoscopy was carried out, and from the accumulated data we are of the opinion that endocervicitis plays a very unimportant role in the production of bladder infections. If lymphatic migration is of such common occurrence, why does not carcinoma of the cervix metastasize more frequently to the bladder? Cystoscopy of 413 patients with carcinoma of the cervix disclosed bladder involvement in only 54, or an incidence of 13.1 per cent.

An interesting invasive lesion of the bladder from a gynecologic focus has been reviewed, namely endometriosis. This lesion is of common occurrence, and when hematuria occurs at the time of menstruation a diagnosis can be readily made. The development and maintenance of this ectopic endometrium is dependent on ovarian activity. When there is widespread involvement of the intestine, rectovaginal septum or bladder, oophorectomy may be the procedure of choice, thus avoiding a difficult and often hazardous operation.

ABSTRACT OF DISCUSSION

DR. NELSE F. OCKERBLAD, Kansas City, Mo.: Jenkins at Yale, whose work on monkeys proved that the endocrine theory is correct, has made a contribution that will live as a starting point of the explanation of pyelonephritis of pregnancy. One point that I would like to stress is the real danger of the indwelling urethral catheter. I had 2 patients that wore indwelling catheters for periods of five to seven weeks. One of these patients one night suddenly started to bleed into the bladder. Before anything could be discovered or done about it the patient died. The autopsy showed that there was a communication between the right ureter and the right common iliac artery. Just about three weeks later a similar case occurred. The nurse on the floor said "This is just like the first one." The patient was brought to the operating room and the incision was made, exposing the area; a communication between the right common iliac artery and the ureter was found and the artery was closed by suture, the ureter was closed and the patient's life was saved, showing that an observant nurse can be of great help. A woman aged 32 was referred to me recently by a gynecologist because of an obstruction to the urethra. There was a large mass between the bladder or the floor of the bladder and the anterior vaginal wall. This proved to be a large cyst, one of those remnants of the duct of Gartner. It was dissected out and found to contain about 300 cc. of clear fluid. Diverticulosis of the urethra is a disorder that urologists are constantly seeing. I have seen 7 cases of diverticulum of the urethra, in 1 of which was a papillary carcinoma causing complete obstruction of the urethra. This patient, however, died of another disease and the specimen obtained was unique. Many of us doing urology also repair vesicovaginal fistulas. Here is a case in which a woman had a bladder that was torn wide open from the cervix clear out through the urethra. She had no urethra. I repaired the fistula and got her down to a little tiny opening which served as a urethra. She didn't leak any at night, but in the daytime she leaked some, so I wanted to go ahead and finish the operation and make her a urethra. While I was thinking about how to go about it she came back and said she wasn't going to have another operation for she had solved the problem. I asked her how she had done it. "Well," she said, "I went to the ten cent store and got a rubber ball just the right size and inserted it in my vagina." It pressed right against the symphysis and acted as a valve and kept her dry and she said she'd have no further operation and the situation was perfect.

DR. VINCENT J. O'CONNOR, Chicago: We have all seen the changes in the female urinary tract which accompany pregnancy and the presence of large pelvic tumors. Those who are interested in these changes which accompany pregnancy are in general agreement that they are due to a combination of hormonal influences with the added mechanical pressure on the ureters exerted by the gravid uterus. We are frequently confronted with the problem of "stress incontinence" in women. The majority of these patients have a definite relaxation of the pelvic floor with incompetent vesical sphincters. In most instances this condition has been preceded by multiple pregnancies. The cause and treatment of this condition are self evident. We are frequently consulted by women who have never been pregnant, who are in the late forties or fifties and who have pronounced stress incontinence but who have no decided relaxation of the pelvic floor. Urethrosopy and cystoscopy show no definite evidence of an irritative factor or relaxed sphincter condition which might account for the symptoms. We must first rule out any associated urinary tract infection, chronic interstitial type of bladder neck infection or any cause of urethral or sphincter irritability with loss of muscle tone. The possibility of neurogenic disease which accounts for a certain percentage of these instances and the exact nature of the underlying lesion may be easily overlooked without a careful neurologic examination. In many of these patients I have insisted on a procedure comparable to the Kelly sphincter reefing operation and in practically every instance the normal bladder continence was restored. A problem which frequently arises in urology is that due to the late radiation effects on the bladder and ureters in women who have been irradiated for various pelvic lesions. These changes vary from sclerotic lesions of the bladder resulting in an interstitial cystitis to strictures of the ureter and granulomatous lesions of the bladder wall, which often give the appearance of primary neoplasms. These irradiation effects may be late in their inception for from one to ten years. They are apparently due to gradual blood vessel contracture with the resultant granulomatous lesions. All patients who have had pelvic irradiation and who subsequently develop urinary dysfunction should be carefully studied from the urologic point of view. I not infrequently have seen patients when I was definitely sure that endometrial invasion of either the lower end of the ureter or of the bladder was present. However, in most of these patients and following castration or irradiation the lesions have disappeared and while there has been strong presumptive evidence of the endometrial urinary invasion I have not been able to prove it.

DR. J. M. HUNDLEY JR., Baltimore: It is unwise to leave the catheter in the ureter longer than forty-eight hours during the later weeks of gestation, for its presence tends to precipitate the onset of labor. We too find stress incontinence a troublesome problem. As a rule we find that this condition exists in women past the menopause and in those who have had trauma from childbirth. With the menopausal group the urethral tube is normal, as is the vesical neck, and frequently the only pathologic condition noted is that of trigonitis. The treatment of this condition in this group of patients consists in sedation, as frequently the patients are of a highly nervous type, and then bladder instillation of silver nitrate solution 1:1,000 biweekly. If the instillations do not give relief, topical application of silver nitrate 1 to 3 per cent is made directly to the trigone through the Kelly cystoscope. We have never operated on a patient in this group, feeling that operation is contraindicated. Cure of the patient with stress incontinence due to lacerations resulting from childbirth is as rule comparatively easy, for the difficulty here is at the vesical neck. The procedure we carry out is one devised by the late Dr. Howard A. Kelly, which consists in buttressing and supporting the tissues about the internal urinary meatus. With this procedure the repair of a frequently associated cystocele is carried out and as a rule excellent results are obtained. There are many intricate operations advised for the cure of stress incontinence, particularly when there is definite relaxation at the internal urinary meatus. However, as a rule simple plicating and buttressing of the tissues suffice.

PRECOCIOUS SKELETAL DEVELOPMENT

ROGER L. J. KENNEDY, M.D.

ROCHESTER, MINN.

In clinical pediatrics, estimation of the degree of skeletal development is frequently carried out by comparing the roentgenogram of a portion of the skeleton with one of a similar portion of the skeleton of an average or normal child of the same age. In actual practice the number of the bones of the wrist and hand and their degree of development are most widely used for such comparison.

It is recognized that well known standards such as those of Todd,¹ Flory² and Engel and Runge³ must be used with allowances for variations within the norm. Although such standards may be unsuitable for strict investigational purposes they may be used to determine whether skeletal development is grossly retarded, normal or grossly advanced. This report is not concerned with minor variations from the normal or average.

Some conditions, notably cretinism, are known to be accompanied by retarded skeletal development. A good deal has been written about such retarded development. Although it has been the subject of extensive study, precocious skeletal development or early maturation has been less emphasized than has retarded development.

The results of experimental work in this field on animals can be interpreted as only suggestive when applied to conditions in the human subject.

The clinical histories of a series of children with precocious skeletal development who have been observed during the past few years have been reviewed to determine (1) in what conditions precocious skeletal development occurs and (2) the factors which may be responsible for skeletal precocity.

In respect to the factors which may be responsible for the skeletal precocity, data concerning the probable role of endocrine disturbances are incomplete. In some cases the amounts of 17-ketosteroids excreted in the urine were determined. In other cases such determinations were not considered essential to diagnosis or treatment and hence were not made.

The histories of 23 patients were reviewed. The patients may be divided into four groups. The first group includes 3 patients with proved adrenal cortical tumor (table 1). In 1 of these 3 cases in which the excretion of 17-ketosteroids was studied before operation, the excretion was 170 mg. in twenty-four hours, a value far in excess of normal. It is pertinent at this point to repeat some of the facts regarding the 17-ketosteroids which have been emphasized by Talbot and his associates⁴ and by Engstrom, Mason and Kepler:⁵ that the 17-ketosteroids which have their source in the adrenal glands and testes of males and in

the adrenal glands of females are not all androgens. Conversely, androgens are not all 17-ketosteroids. The determination of the excretion of 17-ketosteroids, however, usually gives a rough index of androgenic activity. Other patients not included in this series had proved adrenal cortical disease but did not show precocious skeletal development.

The second group (table 2) includes 12 cases in which hyperplasia of the adrenal glands was either proved or, because of the clinical and laboratory evi-

17	♂	4	6	Mongolian idiot; treated with glandular products for 3 years
18	♀	9	14	Thrombocytopenic purpura; treated with testosterone propionate

were mongolian idiots. One of these 2 patients had been treated for three years with desiccated thyroid glands and 1 had received a variety of endocrine products for three years. The third patient in this group had thrombocytopenic purpura and had been treated with testosterone propionate. She showed unmistakable evidence of precocious skeletal development. Although evidence in support of the idea that the advanced skeletal development was a result of endocrine therapy is lacking, the condition of the skeleton in these cases indicates what may result from such medication. The basis for the employment of androgenic substances in the treatment of slipped epiphysis of the head of the femur is indicated by the findings in the third case just mentioned.

The fourth group (table 4) included 5 patients with miscellaneous disorders. One was a child aged 10 months who was brought to the Mayo Clinic because of vomiting and diarrhea. An incidental finding was the presence of bony development that would be normal for a child 2 to 3 years of age. The second patient was a girl who was obese and of large stature. The third was a boy 2 years of age who was brought to the clinic because of anomalies of the eyes. His bony development was approximately that of a child 6 years

TABLE 4.—*Miscellaneous Conditions Without Apparent Adrenal Cortical Disease*

Case	Sex	Age, Yrs.	17-Ketosteroids, Bone Age, Yrs.	17-Ketosteroids, Mg. Excreted in Urine in 24 Hrs.	Clinical Diagnosis
19	♀	5½	2-3	Vomiting and diarrhea
20	♀	9	10½	Obesity; large girl
21	♂	2	6	Anomaly of eyes
22	♀	9½	20	Hemangioma of left orbit and cheek; repeated treatment with radium
23	♀	6	13	1.75	Albright's syndrome

of age. The fourth patient had a hemangioma of the left orbit and cheek. Radium had been applied repeatedly to the affected parts. The last patient in this group was a girl aged 6 years who had the characteristic features of Albright's syndrome, namely sexual and somatic precocity, pigmented regions in the skin and cystic changes in the bones. Although the patient was only 6 years of age her skeletal development was that of a child of 13 years.

In surveying the entire series of cases, certain facts become evident. The first of these is that precocious skeletal development is not a peculiarity of any single clinical syndrome. Although it was found in some cases of adrenal cortical disease with increased excretion of 17-ketosteroids, in other cases of the same condition I have found that skeletal development is within normal limits. The variety of conditions represented in the four groups of cases indicates that precocious skeletal development may be found with or without obvious endocrine disorders and that it may follow administration of endocrine preparations.

One may conclude from the foregoing evidence that known factors such as the androgens may exert effects on the skeleton which lead to precocious development or premature maturation but that such effects are not inevitable in all cases in which their excretion in the urine is increased above normal. Furthermore, it is reasonable to conclude that another factor or other factors may operate together with, or independently of, the androgens to account for skeletal precocity.

ABSTRACT OF DISCUSSION

DR. JOHN R. VONACHEN, Peoria, Ill.: I sometimes wonder if there is really such a person as a normal child, that is, one who conforms to a standard or regular form. Even the healthiest of children cannot be expected to conform to any one given type. Papers like this call attention to variations in growth and development and, of course, this contributes a great deal to the understanding of both sick and healthy children. Because of the differentiation between health and disease we must have at our disposal an understanding of what variations from the average are consistent with health and which point to the presence of disease. Routine physical examinations offer little chance for any detailed estimation of bone development. Generally measurements give only an approximate estimation of total growth. In doubtful cases, of course, we must resort to the roentgenogram. In the laboratory much work has been carried out concerning the roentgenologic estimation of healthy growth and development of bones. The fact that various centers of ossification appear at different ages beginning before birth and continuing to the age of 25 affords an ideal means for checking the progress of growth and development of the skeleton. At the same time we have the opportunity of studying the deleterious effects of previous disease processes of different age periods. I think that Dr. Kennedy has shown that there is no common denominator in this group. Evidently precocious skeletal development as far as is known is not due to a specific factor any more than retarded skeletal development is. However, the x-ray examination of carpal bones may be a practical help in clinical work, in that the absence of skeletal precocity may come with the presence of certain underlying conditions.

Number of Hospitals in New Zealand.—In accordance with the provisions of the Social Security Act, New Zealand is divided into forty-five hospital districts. In each district a board is elected which provides certain types of institutional and extra-institutional medical and nursing service. Under the jurisdiction of each board there is at least one public hospital. These hospitals vary in size and the nature of the facilities afforded according to the density and composition of the population served. There are approximately 160 public hospitals, with a combined capacity of approximately 12,200 beds. Included in this number are the general hospitals, hospitals for the treatment of infectious diseases, tuberculosis institutes, homes for convalescents, charitable institutions, and homes for the aged. In addition to these public hospitals there are 332 private hospitals with a combined capacity of approximately 3,000 beds. On the basis of these figures it is estimated that there are 97 beds per 10,000 of population, which figure is identical with the number of beds available in the United States.—Simmons, James S.: *Global Epidemiology*, Philadelphia, J. P. Lippincott Company, 1944.

ARILD E. HANSEN, M.D.
GALVESTON, TEXAS

This is a brief preliminary note, as of Nov. 7, 1944, concerning 69 infants with manifest early congenital syphilis who have been treated with sodium penicillin by the university groups at Baltimore, Philadelphia, Galveston and New Orleans. Penicillin was administered intramuscularly in saline solution every three hours in sixty injections over a seven and one-half day period. Total dosages used ranged from 16,000 to 32,000 Oxford units per kilogram of body weight. No other antisyphilitic treatment was given.

Preliminary Results of Penicillin Therapy in Infantile Congenital Syphilis

Thirty-Nine Infants Followed for Four to Twelve Months

	Cases	Per Cent
Clinical results:		
Course uneventful	37	
Clinical relapse...	2	
Serologic results:		
Reversed to negative...	21	54
Reversed to doubtful....	4	10
Still positive but titer declining.	9	23
Serologic relapse...	5	13

In 34 of these 69 infants reactions occurred during treatment. Nearly all of these reactions were mild, consisting of moderate fever beginning on the first or second day of treatment and seldom lasting longer than three days. One infant, forty-eight hours after treatment was begun, suddenly developed severe, nearly fatal collapse. Three infants died during or soon after treatment (twenty-four hours, seven days and nine days after penicillin was started); all of these had active syphilitic lesions, were under 2 months of age and were in poor general condition. Two other infants died five weeks and fourteen weeks after penicillin; whether the latter deaths were directly or indirectly due to penicillin or syphilis is not known.

In general, the immediate response of early congenital syphilis to penicillin has been gratifying. Cutaneous and mucous membrane lesions have healed during or shortly after treatment; rhinitis has been somewhat more persistent, healing in from two weeks to two months. All dark field positive lesions have become negative within twenty-four hours after the start of penicillin therapy. Roentgenographic evidence of osteitis disappeared in two to six months, i. e. at about the same rate expected after metal chemotherapy. Regression of hepatic, splenic and lymph node enlargement, though

variable, was usually complete by three months. If abnormal spinal fluid findings were present initially, these have returned to normal in all cases in from eight days to six months.

Of the 69 infants, 39 have been followed from four to twelve months. Twenty-five of these 39 now are physically normal and show doubtful or negative serologic tests (21 negative, 4 doubtful). In 9 of these 39, quantitative serologic titers are either stationary at moderately high levels or slowly declining; these infants also are well. Serologic relapse has occurred in 5 infants, and clinical relapse in 2 of these 5. Serologic relapse occurred from three to six months after treatment, and clinical relapse in each case at six months.

The dosage schedules so far employed have corresponded to a total dose of 1 to 2 million units in seven and one-half days for an adult with early acquired syphilis.

The results so far obtained in infants indicate that the present total dose and time-dose relationship schedule is not entirely satisfactory. Other modifications of this schedule should be studied with due attention to analogous results secured by various schedules in early acquired syphilis in adults. For the present, we believe that an increase in total dose with the same time-dose relationship should be tried first. Accordingly, we recommend temporarily a total dose of 40,000 Oxford units per kilogram of body weight, given in sixty intramuscular injections over a seven and one-half day period.

Attention is called to the vital necessity of adequate supportive care of acutely ill infants.

Definite relapse, serologic or clinical, should be retreated at double the original dosage. A relapse is defined as either a persistently rising serologic titer or clinical evidence of progression of the disease. Persistent positivity of the blood serologic test alone is not yet to be considered an indication in itself for retreatment. A detailed report of these and additional cases will be made by this group at a later date.

SUMMARY

Penicillin is an effective agent in the treatment of infantile congenital syphilis, but the optimum method of its use has not yet been defined.

Clinical Notes, Suggestions and New Instruments

THE MESTER (SALICYLIC ACID) TEST FOR RHEUMATIC DISEASES

JAMES W. WOODS JR., M.D., AND BERNARD I. COMROE, M.D.,
Resident in Medicine and Chief of Arthritis Clinic, Respectively,
Hospital of the University of Pennsylvania
PHILADELPHIA

There is no reaction which one may apply to rheumatic subjects comparable to the tuberculin or Wassermann reactions. If such a test could be found, it might help in eliminating many of the pitfalls and difficulties in the differential diagnosis of the rheumatic diseases.

Mester described a test which he believed had a high specificity for "rheumatism." This consists in the injection of 1.0 cc. of 0.1 per cent salicylic acid in sterile water in five wheals of 0.2 cc. each into the flexor surface of the forearm in a fasting, resting subject. The latter precautions were taken because any change of posture or physiologic activity may produce a rise in the basal count of 60 to 100 per cent.¹

J. Pepper, O. H. P., and Farley, D. F.: *Practical Hematological Diagnosis*, Philadelphia, W. B. Saunders Company, 1933.

This report represents work done under several contracts recommended by the Committee on Medical Research of the Office of Scientific Research and Development and the respective universities represented by the authors.

From the Tulane University School of Medicine (Drs. Platou and Hill), the University of Pennsylvania School of Medicine (Dr. Ingraham), the Johns Hopkins University School of Medicine (Dr. Goodwin) and the University of Texas School of Medicine (Drs. Wilkinson and Hansen).

The white blood cell count is determined prior to the injection and thirty minutes later. A positive test—i. e. denoting rheumatic infection—consists of a decrease of more than 15 per cent in the white blood cell count at the end of thirty minutes.

Mester believed that the reaction was positive in every kind of rheumatic infection not only of the joints but also of the heart, serous membranes, nerves and eyes. He found a positive reaction in 98 per cent of rheumatic patients, while all of his controls were said to give negative results. He thought that the test would be of value in the detection of malingering in rheumatic disorders.²

Lenoch³ concluded that the test was a probable addition to our method of diagnosis of rheumatic diseases but found that it was far from infallible. The test was negative in degenerative joint disease. Lenocho warned against making a diagnosis of rheumatic joint pains or myalgia solely with the aid of this test.

Copeman⁴ and Green and Freyberg⁵ could not confirm Mester's findings and did not find that the test helped in the diagnosis of rheumatic diseases. They noted negative reactions in frank rheumatic disease and positive reactions in nonrheumatic conditions. Only 1 of Copeman's patients had rheumatoid arthritis, although 13 had acute rheumatic fever.

We attempted to evaluate the reliability of the Mester test in active rheumatic fever, in active rheumatoid arthritis and in nonrheumatic controls. These individuals all had increased sedimentation rates, and 7 of the group of 9 patients with rheumatic fever were febrile at the time of the test while 5 of the 16 patients with rheumatoid arthritis had an elevation of temperature. The control group of 20 patients was taken from the medical wards; 4 of these individuals had increased sedimentation rates and 6 were febrile.

Only 2 of the patients with rheumatic fever showed significant drops of more than 15 per cent in the leukocyte count; 2 showed increases of more than 25 per cent and the remainder presented little variation. In the group with rheumatoid arthritis, 5 showed a drop in leukocytes of 15 per cent or more and 5 showed a rise of 15 per cent or more. In the control group 2 showed a significant decrease and 3 showed a significant increase in the leukocyte count thirty minutes after the test. It was found that there were no significant differences among the three groups (rheumatic fever, rheumatoid or control patients) either with or without consideration of the direction of change of the leukocyte count.

It was concluded that the Mester test for rheumatic diseases is wholly unreliable as an aid in diagnosis or differential diagnosis.

PURULENT PERICARDIAL EFFUSION TREATED WITH PENICILLIN GIVEN INTRAPERICARDIALLY

A. W. WISE, M.D., ROCK ISLAND, ILL., AND
L. E. SHAFER, M.D., DAVENPORT, IOWA

M. O. M., a white woman aged 31, was admitted to St. Luke's Hospital on April 5, 1944 with a story of fever, cough, dyspnea, chest pain, palpitation and slight hemoptysis of about four days' duration. The patient had been treated at home during this time, with a diagnosis of lobar pneumonia. She was acutely ill and apparently getting progressively worse.

The physical examination revealed that the breath sounds in the left lower chest were high pitched and tubular in character. Whispered voice and spoken voice were both greatly increased over the same area. The percussion note was dull over the entire left lower lung field. The heart tones were very faint in character and were scarcely audible even though the patient was very thin. Tension was 108/70. The heart was enlarged to the midaxillary line on the left and 3 cm.

beyond the sternum on the right. A tentative diagnosis of left lower lobar pneumonia with associated pericardial effusion was made.

The x-ray examination showed definite consolidation in the left lower lobe. The heart was greatly enlarged to the left and to the right and appeared to be typical of pericardial effusion. The laboratory examination showed 13,650 white blood cells and 4,600,000 red blood cells. Hemoglobin was 11.5 Gm., with a differential of 80 per cent neutrophils and 20 per cent lymphocytes. The urinalysis showed a trace of albumin, with no other abnormalities. Blood was drawn at this time for a culture, which was subsequently negative. Sputum could not be typed, possibly because sulfadiazine had been given for four days before entrance to the hospital, but numerous pneumococci were seen. The treatment consisted of fairly large doses of sulfadiazine, which had also been given before the patient's entrance to the hospital. She was maintained on 1 Gm. of the drug every four hours for five days. Her condition became progressively worse, and dyspnea became extreme. Oxygen was given by B. L. B. mask and the patient was fully digitalized. All through this period her blood pressure was maintained fairly well, and it was thought inadvisable to do a pericardial paracentesis. The temperatures were fairly steady in the neighborhood of 103 to 104 F.

At this time we were fortunate enough to obtain a supply of penicillin for use on this patient. It was started intramuscularly and 15,000 Oxford units was given every three

Clinical course. S, sulfadiazine; P, penicillin; IP, intrapericardial penicillin.

hours, night and day. The sulfadiazine was discontinued at this time, and after three days of penicillin the condition of the patient had not changed very much. It was then decided to give at least one dose of penicillin intrapericardially. A pericardial paracentesis was done and about 70 cc. of turbid, definitely cloudy, blood tinged fluid was removed from the pericardial sac at that time. Then 40,000 Oxford units of penicillin in about 30 cc. of isotonic solution of sodium chloride was introduced directly into the pericardial cavity. The patient suffered no ill effects from this procedure, and within sixteen hours after this time the temperature dropped to normal and, with the exception of an occasional flare up, remained normal for the duration of her illness. Penicillin was continued intramuscularly in decreasing doses for four to five days. The pericardial fluid was inadvertently disposed of in its course through the hospital to the laboratory, and thus one must be forced to rely on our clinical judgment to say whether or not pneumococci could have been grown from it. However, it was definitely a purulent fluid and was removed from a pericardial effusion secondary to a lobar pneumonia. The patient's hospital course was uneventful for the remainder of her stay, and she was dismissed as cured on May 9, her thirty-fourth hospital day.

In our minds this case definitely represents a purulent pericardial effusion, secondary to a lobar pneumonia, which failed to respond to sulfadiazine or intramuscular doses of penicillin but which responded in dramatic fashion to penicillin when given intrapericardially.

AUSTIN SMITH, M.D., Secretary.

DYSENTERY BACTERIOPHAGE

REVIEW OF THE LITERATURE ON ITS PROPHYLACTIC AND THERAPEUTIC USES IN MAN AND IN EXPERIMENTAL INFECTIONS IN ANIMALS

HARRY E. MORTON, Sc.D.

AND

FRANK B. ENGLEY JR., M.S.

PHILADELPHIA

Within the last ten years two reports on the nature and use of bacteriophage have appeared in *THE JOURNAL*. The first review was by Eaton and Bayne-Jones¹ and the second by Krueger and Scribner.² Both of these reports covered all bacteriophages which had been used therapeutically. There may be a fallacy in drawing conclusions from the action of one bacteriophage and attempting to predict the behavior of bacteriophages in general. Some of the conclusions arrived at by Krueger and Scribner did not appear to apply to dysentery phages and so we have found it necessary to review the literature on the use of dysentery phage. This review, along with work reported since the previous reviews, presents dysentery phage in an aspect different from the impression gained from the two previous reviews.

REVIEW OF THE LITERATURE ON THE THERAPEUTIC USE OF DYSENTERY BACTERIOPHAGE

In order to evaluate the effectiveness of dysentery bacteriophage, or any other agent, in the treatment of bacillary dysentery it is necessary to demonstrate dysentery bacilli, the causative micro-organisms, in every patient studied. Moreover, it is important to determine whether or not the preparation of dysentery bacteriophage to be used therapeutically is active against the dysentery bacilli isolated from the patient. This can be done conveniently in vitro. There are differences between strains of bacteriophages as there are between different strains of bacteria. If one preparation or strain of dysentery bacteriophage does not act against a particular culture of dysentery bacilli, other strains or preparations from different sources may do so. An outstanding feature of bacillary dysentery in man is that the mortality is not very great, so, as Seidmayer³ has pointed out, one cannot take the reduction in mortality as a criterion of bacteriophage therapy. He suggests that the criterion of cure should be the time when the dysentery bacilli disappear from the stool. That is desirable because in the treatment of bacterial infections one is interested not only in ridding the patient of his symptoms but also in ridding him of

the pathogenic micro-organisms so as to prevent a recurrence of the disease or the transmission of the micro-organisms to susceptible individuals. Using as the criterion of cure the time when dysentery bacilli disappear from the stool involves the difficulties of growing dysentery bacilli from stools which also contain a dysentery phage. Micro-organisms often fail to grow in cultures when a specific bacteriophage is also present in the specimen. This is a recognized difficulty in the laboratory diagnosis of bacillary dysentery because many patients possess a natural dysentery phage in their stools, especially during the later stages of the infection. It would be, even more, a complicating feature if dysentery phage was administered to the patient.

Kligler, Oleinik and Czazkes⁴ have described a technic for culturing dysentery bacilli from specimens containing dysentery phage. It is based on the observation that dysentery phage is inactivated by high dilutions of solution of formaldehyde at a faster rate than are dysentery bacilli. Stools suspected of containing a mixture of dysentery bacilli and dysentery phage are mixed with equal volumes of dilute solution of formaldehyde so as to give a final concentration of solution of formaldehyde U. S. P. 1 to 10,000 and 1 to 7,500. Cultures of the stool suspensions are streaked on solid mediums immediately, and about six, eighteen and twenty-four hours after mixing with the solution of formaldehyde. An exposure of six, twelve or eighteen hours to the concentrations of solution of formaldehyde mentioned causes an inactivation of the dysentery phage and allows the dysentery bacilli to grow. After twenty-four hours' exposure the dysentery bacilli begin to be killed by the solution of formaldehyde. This improved technic should be valuable in a more accurate laboratory diagnosis in cases of dysentery and should be helpful if dysentery phage is being administered to the patient.

Since the issue of whether or not dysentery phage is of value as a therapeutic agent is still far from settled, the reports, pro and con, will be discussed separately.

(a) The following reports are frequently cited as evidence of the ineffectiveness of dysentery bacteriophage as a therapeutic agent. They are cited here with sufficient information to indicate that they are poor scientific tests or that the information is inadequate to justify the interpretation usually assigned to the reports.

Davison⁵ employed dysentery phage in the treatment of 12 children with bacillary dysentery of the Flexner type. However the stool cultures of 2 of the children were negative for dysentery bacilli and in only 7 cases was the dysentery phage tested and found active against the dysentery bacilli. Of these 7 patients 4 died (ages ranged from 3 to 14 months) and 3 recovered (ages ranged from 2 to 30 months). To the 4 patients who died the dysentery phage was given orally. Of the 3 patients who survived 2 received the dysentery phage rectally and 1 received it orally. Two of the 3 patients who survived received the dysentery phage early in the course of the disease. This may be a very important factor in view of the severity of bacillary dysentery in children. The number of cases is too small to justify a statement as to the ineffectiveness of dysentery phage in the treatment of bacillary dysentery.

Fletcher and Kanagarayer⁶ tried some dysentery phage, provided by d'Herelle himself, in the treatment of 1 case of bacillary dysentery of the Shiga type and 22 cases of the Flexner type in the Federated Malay States. One tube of bacteriophage containing about 2 cc. was given orally at twelve hour intervals for three doses; in some cases a second course of three doses was given, and in others a subsequent dose was given every morning. Daily bacteriologic examinations of the stools were made, but there was no apparent reduction in the number of dysentery bacilli in the stools. Good results appeared to be obtained in the 1 case caused by Shiga's bacillus, and the dysentery phage produced complete lysis of Shiga bacilli in vitro. The dysentery phage was tested in vitro against the Flexner strains and it did not produce complete lysis of the organisms. The authors felt that an attempt should be made to find a bacteriophage which would produce a complete and permanent lysis of the Flexner strains, as was available for the Shiga strains.

Taylor, Greval and Thant⁷ employed bacteriophage therapy in the Rangoon General Hospital during 1928 and 1929 with 14 cases of bacillary dysentery of the Shiga type. A mixed bacteriophage was used at the beginning of the case before isolation and identification of the causative organism. Two cc. was given by mouth three times daily. Eight cases served as controls. There was one death among the 8 controls (reported as 12 per cent mortality) and two deaths among the 14 treated cases (reported as 14 per cent mortality). There was a natural bacteriophage present in all the controls. In another series of 6 cases of Shiga dysentery and 6 controls in 1929 there were no deaths in either group. Again there was a natural bacteriophage present in all the controls. In 1929 there was also a series of 6 cases of Flexner dysentery and 6 control cases. One death from uncomplicated dysentery occurred in each group. In the control group 1 patient also died of dysentery complicated with chronic interstitial nephritis. These series of cases contribute nothing to the evaluation of the therapeutic value of dysentery phage, as the authors state that all the control cases showed the presence of a natural bacteriophage at some period. These results were also reported in part II of the report by Asheshov, Taylor and Morison.⁸

Riding⁹ studied 60 cases of acute bacillary dysentery. Of sixty strains of dysentery bacilli isolated, twelve were not lysed by the standard dysentery phage. Of forty-two strains of dysentery bacilli confirmed serologically, two showed no evidence of bacteriophagy. The clinical course of bacillary dysentery was not altered by dysentery phage given orally. It is possible that the strain of dysentery phage employed was destroyed by the p_{H} of the fluids in the gastrointestinal tract, because 6 normal volunteers took the dysentery phage orally, and the dysentery phage could not be detected in their stools. Riding adjusted some of the dysentery phage with 0.1 normal hydrochloric acid to p_{H} 3 and found that there was no loss in activity of the bacterio-

phage. This, of course, is not comparable to the maximum acidity of the stomach.

Nabarro and Signy,¹⁰ observing the effect of dysentery phage in the treatment of dysentery in children, concluded that the results were disappointing and did not feel justified in recommending it. They used d'Herelle's dysentery phage and stated that it did not contain any Sonne phage. During the four year period of their observations they encountered 87 cases of Sonne infection, 18 cases of Flexner Z and 1 case of Flexner W infection. From the information given, one would not expect beneficial effects of the phage therapy.

In a study of 33 infants less than 2 years old, Johnston, Ebbs and Kaake¹¹ used a polyvalent phage active against Sonne (R and S types), Hiss-Russell and Flexner strains of dysentery bacilli, typhoid-like organisms and some strains of colon bacilli. There were 37 children of the same age distribution in the control group. From 51 of 70 cases, organisms of pathogenic character were isolated. These included ten strains of Sonne, five Hiss-Russell or Flexner, twenty-six Schmitz, sixteen Asiaticus and two paratyphoid B. The dysentery phage was given orally with dextri-maltose solution. Clinically, no difference was observed in the two groups.

Vaill and Morton¹² administered dysentery phage to 21 patients. Only 1 control patient without phage is mentioned. Detailed observations are presented for only 5 cases. Quite justifiably the authors make no statement as to whether dysentery phage is or is not of value in the treatment of bacillary dysentery.

A closer approach to a scientific evaluation of dysentery phage therapy is the report by Kessel and Rose.¹³ Although only 68 cases are included in their data, *Shigella paradysenteriae* Flexner was isolated from each case, verified by biochemical and serologic reactions and shown to be completely lysed by the dysentery phage used for treatment. Three to 5 cc. of dysentery phage was given orally at twelve day intervals with a minimum of three doses. Alternate cases were selected for "phage treatment" and for "controls," care being taken that comparable cases exhibited nearly uniform symptoms. In the 1930 series of cases the lytic property of the phage was tested against each organism isolated before the phage was administered. In 12 of the treated cases the dysentery phage was given on the average of four days after admission to the hospital. No deaths occurred in either the group of 12 treated cases or the control group of 10 cases. The average number of days in the hospital was 11.9 for the patients receiving dysentery phage as compared with an average of 10.1 days for the control group. In the 1931 series of cases the dysentery phage was administered within a few hours after admission to the hospital because it was found that about 90 per cent of all Flexner strains were lysed by the particular strain of dysentery phage in use. The phage later was tested against the organisms for its activity. The average number of days in the hospital was eleven for the phage treated patients as compared with 12.1 days for the controls. There were four deaths in the phage treated cases and three deaths in the control cases. Two of the four deaths in the

treated group and one of the three deaths in the control group occurred within twenty-four hours after admission to the hospital, and it was thought that these cases should be considered as reaching the hospital too late for any treatment to be of value. This leaves two deaths each in both the treated and the control groups.

A recent report by Boyd and Portnoy¹⁴ describes the use in a prisoner of war camp of some dysentery phage which was captured during the retreat of the Axis from El Alamein. The highest titer of the dysentery phage against *Shigella* strains was 1:1,000 by the patch test. Either the test, as employed, was not very sensitive or the titer of the dysentery phage was not very high, because 1:1,000 is not a high titer for a bacteriophage. The authors stated that therapeutically the dysentery phage did not abort dysentery. Of 4,590 controls 6.16 per cent, or 283, developed symptoms of dysentery and 2.96 per cent, or 136 of these, had to be admitted to the hospital. Among the phage treated group of 4,070 prisoners 8.52 per cent, or 347, developed symptoms of dysentery and 3.1 per cent, or 126 of these, had to be admitted to the hospital. On the average it required 9.03 days for the blood and mucus to disappear from the stool of 126 control cases as compared with 9.08 days for 124 phage treated cases. The average stay in the hospital was 19.83 days for the 124 control cases as compared with 16.97 days for the phage treated cases. Based on the figures supplied by Boyd and Portnoy, dysentery phage did not abort dysentery sufficiently to prevent hospitalization or shorten the period when blood and mucus were present in the stools, but it did shorten the average stay in the hospital by 2.86 days. It must be remembered that the titer of the dysentery phage was only 1:1,000 by the method of testing.

Comment.—There are nine reports which are cited at various times as evidence of the ineffectiveness of dysentery phage in the treatment of bacillary dysentery. When these reports are examined few, if any, are free of criticism and should not be considered as contributing any direct evidence as to the ineffectiveness of bacteriophage therapy for the following reasons: Davidson's report really concerns only 7 cases. There was no close comparison in age of the patients, time of administration of the dysentery phage during the course of the infection or the route of administration. Fletcher and Kanagarayer thought they obtained beneficial results in the treatment of 1 case of Shiga dysentery, and there was complete lysis *in vitro* of the Shiga bacilli by the dysentery phage. They suggested that an active Flexner phage ought to be developed because they did not get beneficial results in the 22 cases of Flexner dysentery, nor were the Flexner bacilli completely lysed *in vitro*. The report by Taylor, Greval and Thant should not be considered, because the control groups in two studies were found to have a natural phage, and in another study there were only 6 treated and 6 control cases, with one death in each group. Only 40 of 60 cases in Riding's study should be considered, but he was unable to find the phage in the stools after administering it to normal volunteers. He attempted to determine whether an acid reaction inactivated the dysentery phage and found that it was not inactivated by a reaction of p_H 3. This is not comparable to the maximum acidity to which the dysentery phage might be exposed in the stomach and suggests that the technic employed for detecting the dysentery phage was inadequate. Boyd and Portnoy¹⁴ detected dysentery phage in the blood

serum and stools of 2 normal volunteers who swallowed dysentery phage as well as in 5 patients with bacillary dysentery to whom dysentery phage was given orally. Nabarro and Signy employed a dysentery phage which did not contain any Sonne phage, and yet 87 of 106 cases of dysentery in their study were caused by the Sonne bacillus. It would be expected that they would obtain unsatisfactory results. Johnston, Ebbs and Kaake employed bacteriophage in the treatment of the condition known as "summer diarrhea" in which the causative agent is too obscure to attempt to evaluate a substance like dysentery phage, which may be specific for only dysentery bacilli or even for certain strains of dysentery bacilli. The report of Vaill and Morton contained detailed observations on 5 patients and only 1 control, and even they made no attempt to evaluate dysentery phage as a therapeutic agent.

The reports by Kessel and Rose¹⁵ and by Boyd and Portnoy¹⁴ are the only reports of the nine cited in this section which are worthy of serious consideration. The conclusion which can be drawn from the report by Kessel and Rose is not that dysentery phage is no good in the treatment of bacillary dysentery but that a much larger series than 68 cases must be studied. In one study by these authors there were no deaths and in another study there were two deaths in each of the control and treated groups which could be attributed to bacillary dysentery. They recognized that the mortality in bacillary dysentery was very low and that some criterion other than a reduction in mortality needed to be used. They attempted to use as a criterion of cure the length of time spent in the hospital, but this is not as good for a criterion as the time of the disappearance of the organisms from the stools, as suggested by Seidlmayer.⁹ The results of Boyd and Portnoy are important in that they demonstrate that dysentery phage, after being swallowed, can be detected in the blood serum, feces and urine of the patients. Although phage treatment did not lessen the percentage of individuals requiring hospitalization or shorten the period during which blood and mucus were present in the feces, in the phage treated group the average number of days in the hospital was less by 2.86. The dysentery phage had a titer of only 1:1,000 by the method of testing and its use was entrusted to the prisoners of war.

(b) The following reports are frequently cited as evidence of the effectiveness of dysentery bacteriophage as a therapeutic agent. They are cited here with sufficient information to indicate that they are poor scientific tests or that the information is inadequate to justify the interpretation usually assigned to the reports.

da Costa Cruz¹⁵ employed dysentery phage in the treatment of 24 cases of dysentery. However, a bacteriologic study was made in only 12 of the cases. One case was caused by the Shiga strain, 6 cases by the Hiss strain, 4 cases by the Flexner strain and in 1 case no dysentery bacilli were demonstrated. In 1 of the cases caused by Flexner bacilli the organisms were resistant to the action of the bacteriophage *in vitro* and the bacteriophage was without effect *in vivo*. Two cc. doses of dysentery phage were given by mouth. Some cases showed pronounced benefit in four or five hours, some recovering after one or two doses. In 2 cases the symptoms returned on suspension of treatment but disappeared permanently on resumption of the treatment. Actually only 11 cases of bacillary dysentery are described in the study, and although the phage

treatment appeared to be beneficial there were no controls. In 1924 he¹⁶ reported seemingly equally good results with a larger number of cases.

Spence and McKinley¹⁷ obtained good results with dysentery phage therapy in a comparative study on children. Of the 20 cases in which dysentery bacilli were demonstrated in the stools (9 Shiga and 11 Flexner) 19 of the cases were treated within the first week of the disease with only two deaths ("10 per cent mortality"). There were five deaths in the control group of 12 cases ("40 per cent mortality"). The ages of the children in the treated group ranged from 4 months to 6½ years, whereas in the control group the ages ranged only from 1 to 2 years. The average time of recovery was 12.8 days in the control group as compared with 5.8 days in the treated group.

Choudhury and Morison¹⁸ reported satisfactory results in preventing the spread of an epidemic of dysentery. Nearly all the inhabitants in a neighboring village, Nongsier, had died of dysentery and the people in Sohjárang were becoming ill. Shiga and Flexner strains were isolated from some of the patients. Two cc. of bacteriophage in 4 ounces (120 cc.) of water was given each sick person three times during the first day and subsequently twice daily. There were 18 severe cases with three deaths, no deaths among the 19 moderately severe or 43 mild cases.

Compton¹⁹ reported on dysentery phage therapy in 66 cases, but a bacteriologic study was included for only 6 patients. Although he reported beneficial results, there was during this period of phage treatment a general lowering of the death rate for dysentery which he concluded may have been a coincidence or may have been due to the dissemination of the bacteriophage. In 1942 he²⁰ reported that during the period of 1928-1940 the number of cases of bacillary dysentery in Alexandria was not appreciably reduced but that the case mortality dropped from 20 per cent to 6.5 per cent. The case mortality for typhoid in Alexandria for the period of 1928-1938 remained fairly constant at about 18 per cent. In Cairo, where bacteriophage therapy was not used, the case mortality for bacillary dysentery averaged about 29 per cent for the years 1936-1938.

London²¹ reported that dysentery phage compared favorably with the results obtained by emetine and salines. One of the noteworthy features of the therapy appeared to be the early loss of toxicity. This is at variance with the observation of de Costa Cruz, who stated that dysentery phage did not act on the toxins of the dysentery bacilli and for that reason it was often desirable to combine dysentery phage therapy with immune serum therapy. It was impossible for London to do bacteriologic studies, but no amebas were observed microscopically and the symptoms were those of bacillary dysentery. There were 129 cured out of 141 patients treated with bacteriophage, a mortality of 8.5 per cent. In other tea gardens in the district there were 72 cases of dysentery among the population, with a mortality

rate of 12.5 per cent. The conditions under which the tests were made prevent any scientific deduction from the results as to the value of dysentery phage as a therapeutic agent. Sen²² treated 36 cases of bacillary dysentery in children and reported the results no less striking than d'Herelle's results.

Burnet, McKie and Wood²³ observed that the presence of a highly active phage in some cases appears to determine a rapid recovery. Of 21 patients studied, the stools of 7 who recovered and of 3 who died showed an active phage in the feces, whereas 4 who recovered and 7 who died did not have an active phage in the feces.

McCay²⁴ reported that dysentery phage was successful in effecting a speedy cure in 30 per cent of the cases in which it was used, and in the remaining 70 per cent it appeared to have very little effect clinically. In 111 treated cases there were six deaths (5.4 per cent mortality). In the 120 untreated cases there were thirteen deaths (10.8 per cent mortality). The causative agent was isolated in nearly 50 per cent of the total number of cases.

Davenport and Johnsen²⁵ successfully treated 1 case of accidental infection with Flexner bacilli. The Flexner bacilli were present in the stools at the onset and phage was absent. Five cc. amounts of the Flexner phage were given by mouth for three doses. Flexner bacilli soon disappeared from the stools, and phage appeared. After about one week the stools contained neither Flexner bacilli nor the phage.

Querangal des Essarts²⁶ treated 190 cases of bacillary dysentery occurring during twenty-nine days on board two ships in Brest; however, the causative organism was identified in only 59 cases. There were 16 caused by Shiga, 38 by Flexner and 5 by paradysentery bacilli. A polyvalent dysentery phage was employed in the treatment of 185 cases, 5 cc. being given in alkaline water the first day, 10 cc. on the second and third days and 5 cc. on the fourth day. Blood and mucus disappeared from the stools after the second or third day, and after four days the stools appeared normal macroscopically. None of the cases showed severe toxemia. There were no controls.

Melnik, Khastovitch and Nikhinson²⁷ conducted several studies on the therapeutic use of dysentery phage. The preparation which they used was prepared against the Shiga-Kruse strain and was especially active against that strain. Treatment was a single dose of 5 to 15 cc. orally in saline solution repeated two or three times in some cases. Foods yielding acid products were withheld.

Charnock,²⁸ in summarizing some general procedures for the administration of bacteriophage, suggested that the surroundings should be alkaline.

Melnik, Khastovitch and Nikhinson recommended no food for several hours after the administration of bacteriophage; then large amounts of fluid should be given.

Next day only gradual return to solid food was recommended. They reported that more intense diarrhea may follow the administration of bacteriophage, but it soon disappears. Their first study was in 1929 with 66 cases in which complete recovery was very rapid. Thirteen cases showed complete recovery in twenty-four hours, 25 cases in forty-eight hours, 16 cases in seventy-two hours and 17 cases in four to six days. It proved to these investigators that it is possible to eliminate the illness in two to three days in most cases. It cut down the period of time in the hospital from eight to ten days to two or three days. In another experiment with 19 children, 4 showed no beneficial results yet the Shiga-Kruse bacillus was isolated in every case. They observed that symbiosis of Shiga-Kruse bacilli with enterococci and proteus bacilli lengthened the period of recovery. In a large study there were twenty-seven deaths in 1,059 controls and four deaths in 282 phage treated cases. They reported that the death rate was reduced approximately one half, being 2.5 per cent and 1.4 per cent respectively. Three of the 4 phage treated patients who died were between 60 and 85 years of age. The fourth patient received dysentery phage on the fourth day, recovered in two days and died two weeks later of tuberculosis. These workers regarded the death rate from dysentery in the phage treated group as practically zero; but the mortality rate in the controls was only 2.5 per cent, so it is difficult to use the slight reduction in mortality as a criterion of phage therapy. They claimed that 55.3 per cent of the dysentery patients were out of the hospital four days after treatment, whereas only 18.8 per cent of the controls were out in four days.

Mikeladze, Nemsadze, Alexidze and Assanichvili²⁹ treated 47 cases of dysentery with dysentery phage and experienced three deaths (6.4 per cent mortality), which was about one half the mortality usually observed by ordinary methods of treatment.

Murray³⁰ stated that he treated successfully 146 cases of bacillary dysentery between October 1931 and February 1937 in Shanghai by giving the phage one hour before meals or three hours after a previous meal, preferably in an alkaline medium three times daily.

Haler³¹ employed dysentery phage in controlling dysentery due to the Sonne bacillus in a home for 32 blind children. All those who had been sick, all those unaffected and all the staff received dysentery phage three times daily for a fortnight and thereafter one dose daily. There were no deaths and no bacteriologic study as to whether the phage was active against the organisms for each patient. The sudden cessation of the epidemic is not beyond the realm of a coincidence and, like many of the other reports cited in this section, provides no unequivocal scientific evidence which can be used in evaluating the therapeutic value of dysentery phage.

Soesman³² used a polyvalent dysentery phage in 50 cases (17 adults and 33 children). He reported full recovery and concluded that it was a valuable agent in general practice. Guthof,³³ a battalion medical officer in a German infantry regiment, treated bacillary dysentery with Dysentery Polyfagen (Behring). Good results

were obtained in two to four days in the case of 32 adults and satisfactory results were reported in 3 children with severe infections. No controls were included.

Kliewe and Helmreich³⁴ reported that therapeutically dysentery phage was effective in cases of mild or moderately severe Flexner Y dysentery and it effectively eliminated the carrier state in 16 men. In severe illness there was frequently an exacerbation and only occasionally improvement. Melnick, Khastovitch and Nikhinson²⁷ also reported that frequently the diarrhea was more intense following the administration of dysentery phage but soon disappeared.

Comment.—There are 19 reports which are cited at various times as evidence of the effectiveness of dysentery phage in the treatment of bacillary dysentery. When these reports are examined, few if any should be considered as contributing direct evidence to the effectiveness of bacteriophage therapy, for the following reasons:

The series of cases reported by de Costa Cruz in which bacteriologic studies were made was too small and there were no controls. The series reported by Soesman and by Mikeladze, Nemsadze, Alexidze and Assanichvili are likewise small. Inadequate bacteriologic studies and/or lack of controls form the basis of criticisms of the reports by Choudhury and Morison, Compton, London, Sen, McCay, Murray, Querangal des Essarts, Guthof and Haler. In the report by Spence and McKinley the ages of the children in the control group varied from 1 to 2 years, whereas the ages of those in the treated group varied from 4 months to 6.5 years. In view of the difference in severity of bacillary dysentery in different age groups and the small number of cases, this report cannot be given much weight in evaluating bacteriophage therapy. Burnet, McKie and Wood did not commit themselves on the effectiveness of bacteriophage therapy but merely reported the observation that those individuals who recovered from bacillary dysentery had an active bacteriophage in their feces more often than the patients who did not recover. The single case reported by Davenport and Johnsen cannot, in itself, contribute much in evaluating the effectiveness of bacteriophage therapy in bacillary dysentery, which has such a low mortality in adults.

In the largest number of cases reported in any one study, Melnik, Khastovitch and Nikhinson observed only 2.5 per cent mortality in 1,059 controls as compared with 1.4 per cent mortality in 282 phage treated patients. Of greater significance was that 55.3 per cent of the phage treated patients were out of the hospital four days after treatment, whereas only 18.8 per cent of the controls were out of the hospital in the same time. This might be a better criterion than the decrease in mortality, provided bacteriologic studies were made to insure that the dysentery bacilli had been eliminated from the intestinal tract and that there was not merely the alleviation of symptoms. An interesting observation by these workers was that the symbiosis of Shiga-Kruse bacilli with enterococci and proteus bacilli lengthened the period of recovery. This may be one explanation why dysentery phage may work in 1 case and not in another in spite of the fact that the same strain of the dysentery bacillus may be present and the organism lysed *in vitro* in each case. Many workers have failed to make bacteriologic studies of their cases to make sure that dysentery bacilli were present, so of course

the effect of the association of other organisms with the dysentery bacilli has been overlooked, for the most part. The report of Kliewe and Helmreich did not give sufficient details on the therapeutic trials to warrant any more serious consideration than other reports which have been cited. The curing of the 16 carriers is not a definite accomplishment unless one knows that the dysentery bacilli were actually eliminated from the intestine and not that the workers failed to culture the bacilli in the presence of their specific bacteriophage. Some precautions such as those described by Kligler, Oleinik and Czazkes⁴ would have to be employed in order to obtain unequivocal results.

REVIEW OF THE LITERATURE ON THE PROPHYLACTIC USE OF DYSENTERY BACTERIOPHAGE

Persons of all ages are susceptible to bacillary dysentery. It often is endemic in certain areas and frequently becomes epidemic. Except in infants and debilitated persons the mortality rate is not very great, whereas the morbidity rate may be high. An agent which would prevent infection of individuals with dysentery bacilli would be highly desirable. It becomes even more important when the normally hygienic living conditions throughout the world are disrupted by the conditions brought about by war. Only a few reports deal with the prophylactic value of dysentery phage.

Morison⁸ appears to have been the first to try dysentery phage prophylactically. Two doses of phage were given orally to prisoners during each week of September. During that time 5 cases of dysentery appeared among the 192 prisoners receiving dysentery phage (2.6 per cent morbidity). Among 169 prisoners not receiving dysentery phage, who served as controls, there were 28 cases of dysentery (16.5 per cent morbidity).

Melnik, Nikhinson and Khastovitch³⁵ undertook field trials. The control group, comprising 1,126 children ranging in age from 1 to 15 years and living in the same districts as the other children, experienced 72 infections, or a morbidity of 6.38 per cent. Those treated were divided into two groups. The first group, comprising 692 children ranging in age from 1 to 15 years, received a dose of dysentery phage orally every two weeks, so that during June, July and August each child received a total of seven doses. There were 10 infections, or a morbidity of 1.44 per cent. The second group, comprising 662 children of the same age variation, received dysentery phage plus sterile ox bile under the same conditions. Only 1 child acquired bacillary dysentery, or a morbidity of 0.15 per cent.

Kliewe and Helmreich³¹ tested the prophylactic action of dysentery phage on German soldiers. One hundred and thirteen took 10 cc. of dysentery phage following a dose of sodium bicarbonate in $\frac{1}{2}$ cup of tea or coffee on three successive mornings. In the same unit 250 men served as the controls. None of the treated soldiers developed dysentery, whereas there were 10 cases among the controls.

Boyd and Portnoy³⁴ tested prophylactically on prisoners of war some dysentery phage captured during the retreat of the Axis from El Alamein. The number of prisoners in the phage treated group varied from 672 to 811. The incidence of bacillary dysentery per thousand for the four weeks prior to the administration of dysentery phage was 27.58, whereas the rate per thousand during the four weeks following the adminis-

tration of dysentery phage was 19.5. The number of prisoners in the control group varied from 2,081 to 2,297. The incidence of bacillary dysentery per thousand during the same four weeks prior to administration of dysentery phage to the treated group was 11.35, and the rate per thousand for the same four weeks following the administration of phage to the treated group was 10.29. The number of prisoners in the treated group, which was less than 1,000, was about one third of the number in the control group.

REVIEW OF THE LITERATURE ON THE ACTION OF DYSENTERY PHAGE IN EXPERIMENTAL ANIMALS

It is logical that the *in vivo* action of dysentery phage should be tried in experimental animals following the observation of the lytic action *in vitro*. Such reports in the literature are not very numerous, and a fair proportion of them have not appeared until recently. It is obvious that early workers employed dysentery phage on human beings with no more indication for success than the fact that the phage lysed dysentery bacilli in the test tube. Indeed, many instances are reported in which dysentery phage was used indiscriminately. The improvement in our knowledge on animal experimentation during the last twenty-five years has better demonstrated protective action of dysentery phage *in vivo*. Perhaps it will lead to a more scientific trial of dysentery phage in human beings.

Studying the effect of Shiga phage on infections in rabbits produced by the Shiga bacillus, Kabeshima³⁶ found that after the intravenous injection of Shiga phage the bacteriophage entered the bile and was able to exercise its lytic action on the Shiga bacilli. Otto and Munter³⁷ claimed that they confirmed the basic finding of d'Herelle. Bacteriophagy succeeded even in animal experiments. Appelmans³⁸ found that when bacteriophage was injected into guinea pigs it was present in the spleen for at least five days but not in the liver, kidneys, heart, blood, urine, testicles or lungs. When bacteriophage on bread was fed to mice and guinea pigs, it appeared in the stools but not in the organs of the animals killed. Injected, the bacteriophage passes into the blood stream in a few hours. It is eliminated through the kidney and intestine and thus disappears completely in twenty-four to forty-eight hours. The latter observations are at variance with more recent work in which mice were the experimental animals. Bacteriophage is generally accepted as particulate in nature, and it is quite unlikely for a foreign particle to be completely eliminated from a normal animal twenty-four to forty-eight hours after injection. If the blood was tested in liquid medium for the presence of bacteriophage, the lytic action may have been inhibited or masked by the presence of the blood. If a solid medium was employed, the appearance of the lytic areas may have been so altered after exposure of the bacteriophage to the body fluids as to be not readily recognizable. Perez-Otero (personal observations, Morton and Perez-Otero) observed that when testing the heart's blood from mice for the presence of dysentery phage the plaques sometimes were nearly microscopic in size. The minute plaques were detected with the unaided eye only by proper illumination. More important than detecting the presence of bacteriophage

in the blood is the demonstration of a protective action of the bacteriophage. Arnold and Weiss,³⁹ working with Shiga phage, demonstrated protective action in rabbits. They showed that the bacteriophage was present and active in the blood stream five minutes after injection.

Eliava⁴⁰ failed to find any protective action of dysentery phage when the dysentery phage was injected six hours later or simultaneously with the infecting dose of Shiga bacilli. If the dysentery phage was allowed to come in contact with the Shiga bacilli in vitro even for a few seconds prior to injection into rabbits the animals were protected. Normal rabbit serum or a 5 per cent suspension of rabbit erythrocytes had no effect on the bacteriophage.

After the subcutaneous injection of Shiga phage into guinea pigs, Smirnow and Goldin⁴¹ detected it in the spleen after seventeen days, in the lymph nodes after thirteen days, in the liver after three days and in the blood after two days. In the case of immune guinea pigs the bacteriophage was present after twenty-four hours but not after forty-eight hours, which is to be expected. Specific antibodies combine with the foreign particle when introduced and bring about rapid elimination from the immune animal's body.

The Rakietens⁴² observed that developing chick embryos were killed with relatively small numbers of Flexner bacilli. Death of the embryos could be prevented by dropping a small amount of dysentery phage onto the chorioallantoic membrane five hours after the inoculation of the embryos. There appeared to be a relationship between the survival of the embryos and demonstrable proliferation of the bacteriophage. MacNeal, Blevins and Pacis⁴³ studied the protective action of anti-Sonne phage in protecting chick embryos against infection with *Shigella paradysenteriae*, variety Sonne. The dysentery phage protected 60 per cent of the embryos for four days, compared with a survival of 19 per cent in the controls. Only 2 per cent of the live embryos hatched in the control group, as compared with 28 per cent in the group treated with Sonne phage, which is a significant difference in mortality rates.

By injecting Shiga bacilli intracerebrally, Dubos, Straus and Pierce⁴⁴ were able to produce a meningitis in mice which was fatal in three to ten days. Shiga phage injected into the general circulation of the mice can multiply in the brain of infected mice. Under proper conditions the Shiga phage protects the mice against the fatal infections, and the protection appears to depend on the early establishment of a high bacteriophage level in the infected animal.

Employing white Swiss mice as experimental animals and Flexner strains of dysentery bacilli, Morton and Engley⁴⁵ demonstrated prophylactic and therapeutic actions for dysentery phage. Separate groups of 3 mice each were injected intraperitoneally on successive days for seven days with 1 cc. of dysentery phage containing approximately 1 billion phage particles per cubic centi-

meter. Groups of mice were injected in a similar manner with the same bacteriophage after its lytic activity had been destroyed by heat. On the seventh day all the mice received 10,000 lethal doses of dysentery bacilli (4 bacilli constituted 1 minimum lethal dose). The mice receiving the heat inactivated dysentery phage died, whereas those receiving the active dysentery phage remained well, thus demonstrating the prophylactic action of the dysentery phage. If 1 cc. of dysentery phage was injected intraperitoneally practically simultaneously with 12,000 lethal doses of dysentery bacilli, the mice remained well. A majority of the mice could not be protected if more than three hours elapsed between the infecting dose of dysentery bacilli and the injection of dysentery phage. A strain of dysentery phage developed against the X type of Flexner bacilli protected mice against either the X or the Z type of Flexner bacilli. A strain of dysentery phage developed against the Y type of Flexner bacilli protected mice against virulent bacilli of the Z type. The X and Y dysentery phages lysed the X and Z types in vitro. Dysentery phage developed against the X type failed to lyse in vitro a virulent strain of the Newcastle type of Flexner bacilli, and it also failed to protect mice.

In the therapeutic tests when 2 out of 3 mice were protected, the ratio of phage particles to virulent dysentery bacilli was 1:8 in the case of X phage and the homologous X strain of bacilli, 1:7 in the case of X phage and a Z strain of bacilli and 1:5 in the case of a Y phage and a Z strain of bacilli. It is doubtful whether it would be possible to protect mice or other animals against so many virulent organisms with such a small amount of bacteriophage unless more of the specific bacteriophage was in some way produced within the body of the infected animals. The Rakietens⁴² observed a proliferation of Flexner phage in chick embryos which survived the experimental infections. Dubos, Straus and Pierce⁴⁴ also demonstrated multiplication of Shiga phage in mice experimentally infected with Shiga bacilli. Morton and Perez-Otero⁴⁶ demonstrated quantitatively the increase of dysentery phage in mice. They also demonstrated that the dysentery phage is not eliminated completely from the circulating blood of mice in a couple of days, as was reported by some of the earlier workers. One cc. of dysentery phage containing 1,400,000,000 particles was injected intraperitoneally into mice. After twenty-four hours there were on the average 30,000,000 particles per cubic centimeter of blood as taken from the heart. There was a gradual decrease in the titer of the phage in the blood until seven days after the initial injection, when there were slightly less than 50 particles per cubic centimeter of blood. On the fourth day following the initial injection of dysentery phage, the titer of the phage in the blood of the mice was about 200 particles per cubic centimeter. If the mice at this time were injected with virulent dysentery bacilli not susceptible to the dysentery phage in the test tube, the mice died rapidly without any appreciable increase in the titer of the dysentery phage in their blood. However, if the mice were injected with virulent bacilli susceptible to the dysentery phage in the test tube, the mice remained well and there was an increase by as much as 80,000 fold in the amount of dysentery phage in the circulating blood. Within one hour after the intraperitoneal injection of dysentery bacilli into normal mice, it is possible

to demonstrate a bacteremia. In the case of mice possessing dysentery phage in their circulating blood it is also possible to demonstrate both dysentery phage and dysentery bacilli. The dysentery phage was inactivated with diluted solution of formaldehyde following the technic of Kligler, Oleinik and Czazkes⁴ in order to cultivate the dysentery bacilli successfully. This would imply that bacteriophagy may take place in the blood stream in addition to other places in the animal body.

Comment.—Within a year and a half five reports have appeared demonstrating, without any doubt, the fact that bacteriophagy can take place in vivo and protect developing chick embryos and white mice against fatal infections of dysentery bacilli. Three of the five reports demonstrated that the amount of bacteriophage increases when bacteriophagy takes place in vivo. There is only one report in the literature of the failure of dysentery phage to protect experimental animals. That is the report in the French literature of Eliava, and he was using the Shiga strain, the most toxic of the dysentery bacilli. Kabéshima, Arnold and Weiss and Dubos, Straus and Pierce used the Shiga strain and demonstrated protective action of Shiga phage in vivo, so perhaps the report of Eliava can be ruled out on the basis of personal technic. The earlier reports (Appelmans in 1921 and Smirnow and Goldin in 1931) on the rapid elimination of dysentery phage from the circulation are at variance with what we would expect following the injection of foreign particles into a normal animal. The quantitative work of Dubos, Straus and Pierce and of Morton and Perez-Otero offer proof that dysentery phage is not completely eliminated from the blood in twenty-four and forty-eight hours.

The quantitative work by Morton and Engley is important in that it demonstrates how little dysentery phage is really needed in protecting animals from experimentally induced infections with dysentery bacilli. Most investigators have worked with an amount of phage far in excess of that needed for protection. This may lead to erroneous assumptions of the amount of bacteriophage needed in treating animals larger than mice.

COMMENT AND SUMMARY

The history of dysentery phage may be divided into three phases. The first and most exciting period was the discovery by d'Herelle of the invisible agent which causes transmissible lysis of dysentery bacilli in the test tube. This phenomenon, called bacteriophagy by d'Herelle, was found to take place with micro-organisms other than *Shigella*, so that now it is regarded as commonplace. The second period in the history of dysentery phage was the attempt to use this microscopic parasite for bacteria in the treatment of bacillary dysentery in man. Many of the trials were not carefully planned scientific experiments, so the reports of such trials contributed little if anything toward evaluating dysentery phage as a therapeutic agent. Trials were made without suitable controls. Often a bacteriologic diagnosis of bacillary dysentery was not made; frequently no attempt was made to determine whether the dysentery phage was active against the patient's strain of dysentery bacilli, and often the results were of no statistical importance because of the small number of patients employed. There are about twice as many favorable as unfavorable reports on the use of dysentery phage therapeutically, but the conditions under which the tests were carried out make all the reports, seemingly good or bad, unsuitable for scientific evaluation. Only a few investigators used the dysentery phage

prophylactically, and these reports appear more encouraging than the therapeutic reports. The third phase of the history of dysentery phage has been the in vivo tests, attempts at preventing or curing experimentally induced infections in laboratory animals. The majority of these tests demonstrate that dysentery phage has a definite prophylactic and therapeutic action against experimentally induced infections with dysentery bacilli, both the Shiga and Flexner varieties. All of five recent reports are in agreement in this respect.

The next phase in the history of dysentery phage should be carefully planned prophylactic and therapeutic trials on human beings, taking advantage of the knowledge gained from in vitro tests and in vivo tests on experimental animals. Quite illogically, tests on man were made before the dysentery phage was tried on experimental animals.

In summary it may be stated that:

1. The reports on the therapeutic trials of dysentery phage in man are inconclusive. This is in part due to the nature of the experiments, and the problem of the therapeutic action of dysentery phage must be considered as still unsettled.
2. In experimentally induced infections with dysentery bacilli in laboratory animals, dysentery phage has demonstrated an unmistakably therapeutic action.
3. In therapeutic trials it is necessary to perform a bacteriologic diagnosis and demonstrate dysentery bacilli in each case.
4. Susceptibility of the patients' organisms to the bacteriophage to be employed should be demonstrated in vitro in each case.
5. The criterion for cure should be the disappearance of the dysentery bacilli from the stools. This should be verified by repeated cultures, perhaps employing a technic such as that of Kligler, Oleinik and Czazkes,⁴ which makes possible the cultivation of dysentery bacilli even in the presence of a specific dysentery phage.
6. It is necessary to know that the dysentery phage reaches the dysentery bacilli in an active form.
7. Obviously, suitable controls are necessary. These should be of comparable age and duration of illness and should be free of a natural bacteriophage. Determining the presence of the same pathogenic organism in the controls and its susceptibility to the dysentery phage is not sufficient. Other organisms in the intestinal flora, in both the controls and the treated patients, should also be investigated in case symbiosis with other organisms interferes with the therapeutic effect of bacteriophage, as Melnick, Khastovitch and Nikhinson thought it did.
8. Prophylactically, it has been shown that dysentery phage is capable of preventing bacillary dysentery in man and also capable of preventing lethal infections experimentally induced in laboratory animals.
9. It is necessary to know that the dysentery phage will be active against the strains of dysentery bacilli to be encountered.
10. No lytic action in vitro, no protective action in vivo.
11. A very striking feature of the in vivo action of dysentery phage has been the small amount of dysentery phage required for the protection of experimental animals. A ratio of 1 phage particle to 8 virulent dysentery bacilli has been shown to afford protection in animal experiments.
12. Bacteriophage is unique among antibacterial substances in that, as it is used to destroy bacteria in the animal body, more of the active agent is produced.

SATURDAY, MARCH 10, 1945

THE SUPPLY OF PREMEDICAL AND MEDICAL STUDENTS

The Council on Medical Education and Hospitals has repeatedly urged the necessity for changes in the present policies of governmental agencies, including the Selective Service System, having to do with the education of premedical students. The regulations now in force threaten either a reduction in freshmen enrolments or a far poorer quality of students in late 1945 and 1946. The House of Delegates of the American Medical Association at its meeting in Chicago in June 1944 took official cognizance of the seriousness of this problem and addressed communications to the President, to the War and Navy departments and to the Selective Service System urging that immediate steps be taken to remedy the situation.

Now official notice of this threat to medical education and medical standards has been taken by Senator Allen J. Ellender of Louisiana, who introduced on February 26 Senate Bill 637, which has been referred to the Committee on Military Affairs and which is printed in full elsewhere in this issue (p. 599). The bill includes provisions for the deferment of adequate numbers of premedical students for a period of two years and further provides for the deferment of such numbers of medical students as will be sufficient to supplement civilian sources of students for the maintenance of full classes. The bill also calls for the return to medical and premedical studies of qualified members of the armed forces who have honorably served for a year in the military forces. The latter provision may require some clarification, especially as regards the selection of students for this type of training.

At the time of introducing his bill, Senator Ellender pointed out that the discontinuance of the Army Specialized Training Program and the Navy V-12 Programs would, with a few exceptions, soon result in the cessation of the admission of new students to the freshmen classes in the medical and dental schools. This is a

manpower problem of the present moment, he said, only because a critical shortage of doctors and dentists after 1948 must be anticipated and can be prevented only by action taken now, before September 1945. The army and navy medical corps are certain to need more physicians after the war than were required before this war started; the Veterans Administration will demand eight or ten thousand doctors; physicians will be required to administer the features of the compulsory military training program if that should be provided by Congress and an unknown number of doctors may be wanted to provide the most basic needs of the now occupied countries of Europe, where no medical education has been possible for five or more years. All these requirements are likely to result in a greater deficit of medical men than ever before. The profession is being depleted by about four thousand deaths and an unknown number of retirements annually, Senator Ellender said, and this picture will add up to a very serious situation unless a continuous flow of medical student graduations is maintained annually.

The introduction of this bill represents a great step forward toward the objectives of continued medical education and adequate training of qualified young men. The main outlines of this bill are fully endorsed by the Council on Medical Education and Hospitals of the American Medical Association and the Executive Council of the Association of American Medical Colleges, both of which took part in several conferences on the proposals embodied in the bill with a representative of Senator Ellender. Both medical groups will doubtless participate in the hearings to be held on this bill, the principal provisions of which should receive the full and active support of medical schools and medical societies everywhere.

SENTIMENTALISM ABOUT DOGS

A bull terrier, a family pet, in an unexplained outburst seized and killed the 21 month old daughter of its owners by shaking the child until its neck was broken. The incident may be dismissed as an accident, tragic and horrible. Admittedly large numbers of instances are available in which dogs have been faithful companions, guardians and sometimes martyrs to the interests of their owners. In the present instance the owners of the dog concluded that the dog was dangerous and that the only thing to do was to have him killed. The destruction of the dog is to be accomplished by humane society authorities and apparently is a calmly reasoned act, all the more remarkable in view of the emotional tension in which the stricken parents must be living.

When this decision was reached by the parents, numerous self-styled dog lovers apparently deluged them

with telephone calls, letters and telegrams; one apparently even attempted legal action to save the life of the dog. The total lack of consideration and the crass indifference shown by these busybodies toward the grief and bereavement of the parents is almost unbelievable; yet these are the stuff of which antivivisectionism is made. To them the life of a dog is more important than the life of a child. Their warped mentalities conceive that this dog should be saved and pampered, perhaps to kill another child, certainly to be a constant care, expense and potential menace. The same muddled thinking would deny the use of animals to scientists in the laboratory, preferring that rats, mice, guinea pigs and frogs should live even if the lives of human beings must be lost in consequence.

The deadly influence of antivivisectionism on character, keenly perceived and analyzed by the late Dr. W. W. Keen, is an ever present menace. Uninformed people leave money, sometimes in large amounts, to be spent in cynical disregard of public welfare and public health by conscienceless executive secretaries who fatten on the gullibility of their own clients. Their antivivisectionism functions contrary to the interests of the animals which they profess to serve, for animals also are beneficiaries of animal experimentation. An incident such as that which forms the basis of this editorial serves to reemphasize the difficulties faced by physicians and scientists in attempting to carry out their service to mankind by experiments on animals.

THE PROGRESS OF THERAPY

Physicians, listing the ten most important drugs used in medicine in 1910, chose them in the following order: (1) ether, (2) morphine, (3) digitalis, (4) diphtheria antitoxin, (5) smallpox vaccine, (6) iron, (7) quinine, (8) iodine, (9) alcohol and (10) mercury. Just five years previously the Council on Pharmacy and Chemistry had been established to eliminate from medicine the shotgun therapy based on indiscriminate empirical remedies. Out of their efforts came such works as *Useful Drugs*. The same impetus brought about intensive revision of the *United States Pharmacopeia*, which today, along with *Useful Drugs* and *New and Non-official Remedies*, may be said to constitute the proved armamentarium of the physician.

Tremendous advancement has occurred in the field of therapy since 1910—so great indeed that it is almost impossible to list today ten individual remedies which might be said to be the ten most important or useful in medical practice. In an effort to determine what leaders in medicine might choose as most important in 1945 the editor of *THE JOURNAL* addressed a communication to some of the professors of medicine in

leading medical schools.¹ The largest number of replies put penicillin first. In considering penicillin, however, other antibiotic drugs were added. Certainly the sulfonamides come exceedingly close from the point of view of their application under a wide variety of circumstances. At least five of the physicians consulted placed morphine first on the list of important drugs, yet many added to morphine the names of some of the barbituric acid derivatives. Ether still merits a place on any list of important drugs, but today the anesthetist has access to nitrous oxide-oxygen, cyclopropane, ethylene, local anesthesia, spinal anesthesia and continuous caudal anesthesia as well as the basal anesthetics injected directly into the blood. Digitalis still holds a place among the most important of remedies. The diphtheria antitoxin of 1910 is now supplemented by innumerable antitoxins and vaccines established as specific against certain infections. New on the modern list are blood plasma, whole blood for transfusions, gamma globulin and all of the other substances derived from blood. Little was known in 1910 of the products of glands. Today the life-saving properties of insulin, liver extract, estrogenic and male sex hormones, adrenal and thyroid are unquestioned. Little was said in 1910 about vitamins, but the vitamins must be included in any significant list because of their specific virtues in cases of established deficiencies such as rickets, scurvy, pellagra and beriberi. Questionable on any modern list would be the arsphenamines. If penicillin develops as is anticipated in the treatment of syphilis, the arsphenamines may go far down on any list of important remedies. Since malaria appears to be the most widespread of all diseases on the face of the earth, the quinine of previous generations must be assisted by quinacrine and other specific anti-malarial remedies.

A 1945 list of the most important remedies might be:

1. Penicillin and the sulfonamides and antibiotics.
2. Whole blood, blood plasma and blood derivatives.
3. Quinine and quinacrine.
4. Ether and other anesthetics, morphine, cocaine and the barbituric acid derivatives.
5. Digitalis.
6. Arsphenamines.
7. Immunizing agents and specific antitoxins and vaccines.
8. Insulin and liver extract.
9. Other hormones.
10. Vitamins.

1. Reports were received from David P. Barr, New York; Harry Beckman, Milwaukee; Henry A. Christian, Boston; Arthur C. DeGraff, New York; Harry Gold, New York; Frederic M. Hanes, Durham, N. C.; Tinsley R. Harrison, Dallas, Texas; Ernest E. Irons, Chicago; Chester S. Keefer, Boston; Stuart Mudd, Philadelphia; J. H. Musser, New Orleans; O. H. Perry Pepper, Philadelphia; Hobart A. Reimann, Philadelphia; Austin E. Smith, Chicago; Torald Sellmann, Cleveland, and W. O. Thompson, Chicago.

Physicians of long experience will arise at once to defend iron, iodine, alcohol, mercury and even aspirin. Actually the choice of the most important remedy depends on the condition with which the physician is confronted. For malaria there is no question about the value of quinine or quinacrine; for asthma, epinephrine or aminophylline would seem most important. For amebic dysentery emetine, chiniofon or carbarsone would be the choice. If the patient just happened to have postprandial indigestion, baking soda might be considered the sovereign remedy. One of the experts put common table salt as number 4 on his list and glucose as number 5.

So great then has been the advancement of therapy that the choice of the ten most important remedies in medicine would baffle any assemblage of experts. The physical therapists might well question the entire list. The surgeons and authorities in the field of cancer would have ideas seriously varying from those of the internists. All physicians may well take great pride in all that medicine has accomplished in the past quarter century!

COLLOIDAL PENICILLIN

Penicillin injected intramuscularly or intravenously is rapidly excreted in the urine, an effective therapeutic level in the blood stream rarely being maintained for as long as two hours after injection. In order to prolong the effective concentration in the blood clinicians repeat the intramuscular or intravenous dose at three to four hour intervals or resort to some method of continuous instillation.¹ Several alternate methods of prolonging penicillin action have been suggested by recent experimenters, such as the simultaneous injection of diodrast² or para-aminohippuric acid,³ both of which retard the rate of renal excretion of penicillin. Others have suggested suspending the intramuscular dose in oil or in oil containing 0.75 to 6 per cent of beeswax⁴ or of reducing the rate of local absorption by prolonged chilling of the injected muscle⁵ or by adding epinephrine to the penicillin dose.⁶ Two of these methods have apparently given encouraging clinical results, particularly in the treatment of gonorrhea.

What may prove to be an equally successful method has been suggested by Chow and McKee⁷ of the Squibb Institute for Medical Research, New Brunswick, N. J. They combined crystalline penicillin with human plasma protein to make a large penicillin-protein complex. This

colloid is apparently much more slowly absorbed from the injected muscle and more slowly excreted by the kidneys than is free or unbound penicillin. To make such a combination, 125 units of penicillin per cubic centimeter was added to buffered solutions of human alpha, beta or gamma globulin or to human serum albumin. The mixture was placed in a cellophane bag suspended in phosphate buffer solution. After eighteen to twenty-four hours continuous rocking, the relative penicillin titer was determined in the bag and the surrounding dialysate. Within the limits of the experimental error there was no evidence of a union between penicillin and any of the globulins. Approximately two thirds of the penicillin in the albumin mixture became nondialysable, presumably as a result of physical or chemical union with albumin molecules.

The resulting penicillin-albumin complex was then isolated in a state of at least partial purity by repeated precipitation with 50 per cent alcohol; unbound penicillin is soluble in this concentration. A dry powder was obtained by lyophilization. Unlike the sulfonamide-albumin complex, which is devoid of bacteriostatic properties,⁸ the penicillin-albumin complex possesses full antibiotic powers. Injected intramuscularly into mice, the complex is much more slowly excreted in the urine than unbound penicillin. Since the protein in this complex is normal human albumin, Chow predicts that the penicillin-protein complex will be found to be nontoxic and nonantigenic for man. The therapeutic efficiency of the new colloidal penicillin is now under investigation.

Current Comment

CAMPAIGN TO CHECK AUTOMOBILE BRAKES

The International Association of Chiefs of Police¹ recently announced a campaign of nationwide scope to lead automobile drivers to check their brakes. This program will be conducted between April 15 and June 1. The campaign has been evolved by the police association as a device to focus public attention on the seriousness of the traffic accident situation. When a similar program was started in Michigan one of seven cars failed to meet brake check requirements, and when the program ended only one of twenty-three cars failed to meet such requirements. During the period of the campaign, about 11 per cent of all cars checked had brakes considered inadequate or unsafe. The influence of physicians may well be placed behind this program for its public health importance and as a means of lessening emergency calls in this time of stress.

MEDICINE AND THE WAR

ARMY

NO FURTHER REDUCTION IN SIZE OF ARMY MEDICAL CORPS

The Office of the Surgeon General has advised that its recent action as approved by War Department directive of releasing a few medical corps officers to bring the strength of the corps within the allotted ceiling (THE JOURNAL, Dec. 30, 1944) has been completed. At the present time the strength of the medical corps is within reasonable conformity with the troop basis of the Army, and no further reduction is contemplated until such time as overall planning now in process concerning the projected needs for medical care of the Army can be ascertained and a reduction of medical corps officers made in the same proportion.

Medical Corps officers who will enter on active duty after completing the Army Specialized Training Program in medicine and a suitable internship will during the coming months be used largely to replace those Medical Corps officers who are lost to the service.

ARMY PREVENTIVE MEDICINE OFFICERS MEET

A three day conference of army preventive medicine officers was recently held at the School of Hygiene and Public Health, Baltimore, and was attended by representatives from the Office of the Surgeon General, service commands, army air forces and army ground forces. The purpose of the conference was to present recent developments in research and current policies and to afford ample opportunity for discussion of local preventive medicine problems and their solutions. The conference was opened by Major Gen. Philip Hays, commanding general of the Third Service Command. Topics discussed the first day were immunization, control of infectious diseases and insect control. The presiding officer was Col. Thomas B. Turner, assistant chief, Preventive Medicine Service, Office of the Surgeon General. Topics discussed the second day were problems of sanitary engineering, industrial medicine in the Army, public health aspects of tropical diseases, laboratory services and army veterinary activities. The presiding officer was Col. W. A. Hardenbergh, director of the Sanitary Engineering Division, Preventive Medicine Service, Office of the Surgeon General. Topics discussed the third day were venereal disease control, nutrition in troops, health programs in occupied countries, foreign quarantine in military traffic and medical intelligence. The presiding officer was Lieut. Col. Elliott S. Robinson, assistant chief, Preventive Medicine Service, Office of the Surgeon General.

ARMY HOSPITALS SEEK OCCU- PATIONAL THERAPISTS

A serious shortage of occupational therapists, who play a vital role in the reconditioning of sick and wounded soldiers, exists in army hospitals, in addition to the lack of nurses and trained medical technicians. The Office of the Surgeon General reported that of the 1,800 qualified registered occupational therapists in the country the Army has only 225 and has immediate need for another 225. Openings exist in all parts of the country for this highly important work. Applicants who are employed on a civilian status must be graduates of a course in occupational therapy approved by the Council on Medical Education and Hospitals of the American Medical Association or must be a registered occupational therapist. The approved course has a minimum requirement of at least four years in an approved college. The Civil Service classification is subprofessional 5 and the pay is \$1,800 a year, plus overtime. Applications for employment should be made directly to the Office of the Surgeon General, Washington, D. C., and application forms are obtainable at any post office.

MISSING IN ACTION

Capt. John S. Rodda, formerly of Portland, Ore., has been reported missing in action since Dec. 19, 1944, at which time he was in action in Belgium. Dr. Rodda has been almost constantly in forward and very active areas ever since his D day landing in Normandy with the glider units which followed the parachutists in ahead of the beach landings. He participated in the Presidential citation of his unit for this work and received the Purple Heart because of injuries received when his flak damaged glider crashed. Dr. Rodda graduated from the University of Oregon Medical School, Portland, in 1940 and entered the service July 25, 1941.

Major G. D. Fridline, formerly of Ashland, Ohio, has been reported missing in action since Dec. 21, 1944. Dr. Fridline graduated from Boston University School of Medicine in 1931 and entered the service in October 1940 as commanding officer of Company H, 112th Medical Regiment, Ohio National Guard, and was later assigned to the medical detachment of the 165th Infantry.

Capt. Charles F. Payton, formerly of Birmingham, Mich., has been reported missing in action on the Belgian-German front since January 20. He was stationed at front line first aid stations during much of the fierce fighting of the Belgian bulge. Dr. Payton graduated from the University of Michigan Medical School, Ann Arbor, in 1942 and entered the service Oct. 7, 1943.

TRAINING OFFICERS FOR THE ARMY MEDICAL CORPS

Courses of instruction in internal medicine and medical specialties and in general surgery and surgical specialties which are being set up in army service forces general and certain regional hospitals for army officers will be discontinued at the Mayo Foundation with the completion of the present quarters, according to an announcement at the Office of the Surgeon General.

Officers of the Army Medical Corps will continue in the Mayo Foundation their training in anesthesia, physical medicine and clinical roentgenology according to the usual schedule that has been in operation in these courses.

Courses in maxillofacial and plastic surgery and in other special fields for individual officers will be continued at the Mayo Foundation as requested by the Army or Navy. Over 1,200 officers have participated in the several courses in the Mayo Foundation since they were inaugurated in January 1942. These courses were organized on the assumption that during a twelve weeks period a sufficiently comprehensive review of the general fields of medicine and surgery could be accomplished to conform to the varied needs, experiences and training of the officers.

Following the war it is planned that facilities of the Mayo Clinic will again be utilized for courses on a basis similar to those conducted during the past three years for physicians being detached from military service and for civilian physicians.

WACS TO BE NURSE'S AIDES

As the result of plans to enlist medical Wacs, the recruiting of full time remunerated nurse's aides has been stopped by a War Department directive. Aides already in the service or now undergoing training will be retained. Because of the difficulty of transferring these civilians away from home and home responsibilities, the new plan has been adopted in the knowledge that medical Wacs can be transferred readily to places where there may be an acute shortage of nurses.

The drive has been started to enlist 8,000 Wacs, many of whom are expected to carry on nonprofessional medical work in army hospitals. To help nurses of the Regular Army, 100 medical Wacs are now being assigned to each army hospital.

ARMY NURSE CORPS NEEDS 16,000 NURSES IMMEDIATELY

Major Gen. George F. Lull, Deputy Surgeon General, recently announced that the Army needs 16,000 additional nurses immediately in order to care adequately for wounded and sick American soldiers. Hospital units have been shipped overseas without nurses because of the shortage, which meant that overseas nursing personnel, already overtaxed, had to be drawn on to staff these units. Of the Army Nurse Corps strength of 44,000, about 71 per cent are overseas, some having been in foreign theaters for several years. When the full quota of 60,000 is reached it will be possible to make more effective a rotation plan that will provide much needed change for the overworked nurses who have been away from home for long periods.

AMPUTATION CASES IN THE U. S. ARMY

In a recent report from the Office of the Surgeon General, it is stated that amputation cases in the United States Army reached a total of 6,027 as of January 1945, including 1 triplicate case, the first known in either this war or the first world war. There are no "basket" cases, the term used to denote loss of all four limbs, nor were any reported during the entire course of the first world war.

In the first world war there was a total of 4,403 amputation cases. Of the 6,027 cases in this war, 331 represent double amputations, that is, loss of two limbs. The remainder, or 5,695, are soldiers with one arm or one leg lost. Of the total number, approximately 2,000 cases have been treated at one of the six army general hospitals specializing in amputation cases and returned to civilian life. The hospitals include

Walter Reed General Hospital, Washington, D. C.; Lawson General Hospital, Atlanta, Ga.; Percy Jones General Hospital, Battle Creek, Mich.; England General Hospital, Atlantic City, N. J.; McCloskey General Hospital, Temple, Texas, and Bushnell General Hospital, Brigham City, Utah.

Before discharge, each man is individually fitted with a custom made prosthesis and taught complete use of his artificial limb. Only when he is able to care for himself and take his place in the civilian world is he released from army jurisdiction and medical care.

LIEUT. REBA Z. WHITTLE A PRISONER OF WAR

Lieut. Reba Z. Whittle, formerly of Rock Springs, Texas, has chosen to remain in a German prison camp at Stalag 9 C near Meiningen to care for wounded American prisoners of war, although she is eligible for repatriation. It was reported that when the Germans learned that she was "protected personnel," according to the terms of the Geneva convention, she was given the opportunity to be released. She realized, however, that the wounded American prisoners needed nursing care and she offered to remain to take care of them. Her offer was accepted and she is now a prisoner of war. It is believed that Lieutenant Whittle is the only army nurse who is a prisoner of war in Germany.

COLONEL DUNCAN NEW CONSULTANT

Col. G. G. Duncan, formerly chief of the Medical Service at Thomas M. England General Hospital, Atlantic City, has been assigned as consultant in medicine, Headquarters, Second Service Command, Governors Island, N. Y. He replaced Lieut. Col. Herman Blumgart, who has been assigned overseas.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

REVISE SELECTIVE SERVICE DEFERMENT POLICY

The National Headquarters of Selective Service, in an amendment of Local Board Memorandum No. 115, has revised the procedures relative to the deferment of men under 38 years of age and has designated the Procurement and Assignment Service as one of the fifteen certifying agencies, with the Code No. 15. These procedures will affect (a) civilian interns, (b) civilian residents, (c) members of the professions on the faculties of universities and (d) members of the professions engaged in private practice or otherwise regularly engaged in an activity in war production or in support of the national health, safety or interest.

MEMBERS OF THE PROFESSIONS IN THE AGE GROUP 18 THROUGH 29

A. It is necessary at once for state chairmen to ask employers (universities, hospitals, industries and so on) to make out and submit to the state chairman's office a list, in triplicate, of members of the professions in his establishment who are in the age group 18 through 29 and who are necessary to and regularly engaged in and are indispensable and irreplaceable in an activity in war production or in support of the national health, safety or interest. This includes all those who were on Jan. 1, 1945 classified II-A or II-B. Two sets of three copies each of form 42-A (special-revised) should be submitted for each registrant.

B. Immediately on receipt of forms 42-A (special-revised) the state chairman should, if he concurs that the registrant is essential, (1) certify by signing the originals only and entering the name and Code No. 15 of the Procurement and Assignment Service as the certifying agency; (2) forward one complete set of three copies each of form 42-A (special-revised) to the registrant's local board; (3) forward to the state director of Selective Service in the state of employment the original copy of the second sheet of 42-A (special-revised), with one copy of the lists; and (4) retain, for his own use, two carbon copies of form 42-A (special-revised) and the two copies of the lists.

MEMBERS OF THE PROFESSIONS IN THE AGE GROUP 30 THROUGH 33

The same procedure as outlined in A and B will be followed by members of the professions in the age group 30 through 33, with the exception that forms 42 and 42-A will be used in place of form 42-A (special-revised). Members of the professions in the age group 30 through 33 must be necessary to and regularly engaged in (but not necessarily indispensable and irreplaceable in) an activity in war production or in support of the national health, safety or interest.

MEMBERS OF THE PROFESSIONS IN THE AGE GROUP 34 THROUGH 37

The same procedures as outlined in A and B will be followed for members of the professions in the age group 34 through 37, with the exception that forms 42 and 42-A will be used in place of forms 42-A (special-revised). Members of the professions in the age group 34 through 37 must be regularly engaged in (but neither necessary to nor indispensable and irreplaceable in) an activity in war production or in the support of the national health, safety or interest.

N. B.: 1. The term "interns" as used includes all individuals serving in internships whether or not they have received their degree of doctor of medicine.

2. These procedures are not necessary for individuals who are classified by Selective Service as 4-F. However, this must not be confused with a physical disqualification on application for commission, which is an entirely different thing.

3. Students are not included in these procedures.

Hospitals and other institutions employing civilian physicians under 38 years old are urged to submit to the state chairman of the Procurement and Assignment Service the information requested.

NAVY

INTERNSHIPS AND RESIDENCY TYPE
GRADUATE TRAINING IN
NAVAL HOSPITALS

General rotating internships in naval hospitals were established in 1924. At the present time thirty-eight such hospitals have been approved by the Council on Medical Education and Hospitals of the American Medical Association for internship training on the same standards as those of civilian hospitals.

Under the accelerated program these naval internships consist of a nine months rotating service, providing all interns with three months in each of the three groups of service according to the following schedule:

1. Medicine, neuropsychiatry and clinical laboratory.
2. Surgery, urology, eye, ear, nose and throat and roentgenology.
3. Obstetrics, pediatrics and gynecology.

These internships are acceptable for credit before state boards of licensure to the same extent as similar internships in civilian hospitals.

The Professional Division of the Bureau of Medicine and Surgery, when established last year, began immediately to put into effect an extensive program for graduate medical education of the residency type in naval hospitals. These services are being reviewed by the Council on Medical Education and Hospitals of the American Medical Association for credit before the American boards certifying in the specialties and the American College of Physicians, while the facilities for surgical residencies are also being surveyed by the American College of Surgeons.

Younger medical officers whose graduate training in the specialties may have been interrupted by enlistment may thus continue their training in the formal equivalent of a residency when assigned to the special divisions of these hospitals. The general policy of the Bureau of Medicine and Surgery with regard to opportunities for graduate training in the medical specialties is to be a gradual substitution of this residency type of clinical training through duty assignments in place of the shorter and more didactic or academic "courses" which have long been available. Medical officers desiring graduate training in the specialties, especially if already partly trained, are encouraged to apply to the Bureau of Medicine and Surgery for such assignments on completion of their tours of sea duty. All of the specialties are included in this training because the Navy cares not only for naval personnel but also as far as possible for their dependents, including large numbers of obstetric, gynecologic and pediatric cases.

This program was not an innovation except as an officially recognized procedure. The inclusion of many prominent specialists in the staffs of the large naval hospitals of this country had contributed to the existing high standards of care of patients as well as providing additional opportunities for graduate work for medical officers even prior to the initiation of this formal residency program last year. Appropriate assignment of medical officers according to previous training with opportunities for further training in their chosen specialties is designed primarily to ensure constant improvement in the standards of medical care in naval activities.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Commander George A. Stanbery

The Silver Star Medal was recently awarded to Lieut. Comdr. George A. Stanbery, formerly of Vandalia, Ill., "for conspicuous gallantry and intrepidity while serving as battalion medical officer with the Second Amphibian Tractor Battalion, Second Marine Division, during action against enemy Japanese forces on Tarawa Atoll, Gilbert Islands, Nov. 21-23, 1943. Realizing the urgent need for medical assistance ashore on the morning of November 21, Lieutenant Commander Stanbery personally assumed command of his landing boat and ordered it to land despite the intense, persistent machine gun and anti-boat fire which was driving all small craft back from the beach. On

landing, he immediately joined a hard pressed aid station and, working tirelessly and with complete disregard for his own safety, continually exposed himself to enemy fire in order to evacuate seriously wounded casualties onto amphibian tractors. By his splendid initiative and outstanding professional skill, Lieutenant Commander Stanbery was responsible for the saving of many lives, and his courageous efforts under extremely hazardous conditions were in keeping with the highest traditions of the United States Naval Service." Dr. Stanbery graduated from St. Louis University School of Medicine in 1927 and entered the service March 23, 1942.

Lieutenant Marion Melvin Green

The Legion of Merit was recently awarded to Lieut. Marion Melvin Green, formerly of Stockton, Calif., "for exceptionally meritorious conduct in the performance of outstanding services to the government of the United States as a medical officer prior to and during the operations against enemy Japanese forces on Tarawa Atoll, Gilbert Islands, Nov. 20 to 24, 1943. Assuming the duties of the battalion surgeon, who had been killed, Lieutenant Green efficiently and expeditiously established an aid station on one of the assault beaches and, completely disregarding his own personal safety, worked tirelessly and with expert professional skill in administering medical assistance and evacuating the wounded. By his splendid initiative, cool courage and tenacious devotion to duty under extremely hazardous conditions, Lieutenant Green undoubtedly saved the lives of many who otherwise might have perished." Dr. Green graduated from Stanford University School of Medicine, San Francisco, in 1933 and entered the service in March 1942.

Lieutenant Ralph Atkins Foster
